
Figure 49.27 ■ A wall suction unit.

SKILL 49.2

Oral, Oropharyngeal, Nasopharyngeal, and Nasotracheal Suctioning

PURPOSES

- To remove secretions that obstruct the airway
- To facilitate ventilation
- To obtain secretions for diagnostic purposes
- To prevent infection that may result from accumulated secretions

ASSESSMENT

Assess for clinical signs indicating the need for suctioning:

- Restlessness, anxiety
- Noisy respirations
- Adventitious (abnormal) breath sounds when the chest is auscultated
- Change in mental status
- Skin color
- Rate and pattern of respirations
- Pulse rate and rhythm
- Decreased oxygen saturation

PLANNING

Assignment

Oral suctioning using a Yankauer suction tube can be assigned to AP and to the client or family, if appropriate, since this is not a sterile procedure. The nurse needs to review the procedure and important points such as not applying suction during insertion of the tube to avoid trauma to the mucous membrane. Oropharyngeal suctioning uses a suction catheter and, although not a sterile procedure, should be performed by a nurse or respiratory therapist. Suctioning can stimulate the gag reflex, hypoxia, and dysrhythmias that may require problem-solving. In contrast, nasopharyngeal and nasotracheal suctioning use sterile technique and require application of knowledge and problem-solving and should be performed by the nurse or respiratory therapist.

Equipment

Oropharyngeal, Nasopharyngeal, and Nasotracheal Suctioning (Using Sterile Technique)

- Towel or moisture-resistant pad
- Portable or wall suction machine with tubing, collection receptacle, and suction pressure gauge
- Sterile disposable container for fluids
- Sterile normal saline or water
- Goggles or face shield, if appropriate
- Moisture-resistant disposal bag
- Sterile gloves
- Sterile suction catheter kit (#12 to #18 Fr for adults, #8 to #10 Fr for children, and #5 to #8 Fr for infants)
- Water-soluble lubricant
- Y-connector
- Sputum trap, if specimen is to be collected

Oral and Oropharyngeal Suctioning (Using Clean Technique)

- Yankauer suction catheter or suction catheter kit
- Clean gloves

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how to participate. Inform the client that suctioning will relieve breathing difficulty and that the procedure is painless but may be uncomfortable and stimulate the cough, gag, or sneeze reflex. **Rationale:** *Knowing that the procedure will relieve breathing problems is often reassuring and enlists the client's cooperation*.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Prepare the client.
   - Position a conscious client who has a functional gag reflex in the semi-Fowler's position with the head turned to one side for oral suctioning or with the neck hyperextended for nasal suctioning. **Rationale:** *These positions facilitate the insertion of the catheter and help prevent aspiration of secretions*.
   - Position an unconscious client in the lateral position, facing you. **Rationale:** *This position allows the tongue to fall forward, so that it will not obstruct the catheter on insertion. The lateral position also facilitates drainage of secretions from the pharynx and prevents the possibility of aspiration*.
   - Place the towel or moisture-resistant pad over the pillow or under the chin.
5. Prepare the equipment.
   - Turn the suction device on and set to appropriate negative pressure on the suction gauge. The amount of negative pressure should be high enough to clear secretions but not too high. **Rationale:** *Too high of a pressure can cause the catheter to adhere to the tracheal wall and cause irritation or trauma*. A rule of thumb is to use the lowest amount of suction pressure needed to clear the secretions.

For Oral and Oropharyngeal Suction

- Apply clean gloves.
- Moisten the tip of the Yankauer or suction catheter with sterile water or saline. **Rationale:** *This reduces friction and eases insertion*.
- Pull the tongue forward, if necessary, using gauze.
- Do not apply suction (that is, leave your finger off the port) during insertion. **Rationale:** *Applying suction during insertion causes trauma to the mucous membrane*.
- Advance the catheter about 10 to 15 cm (4 to 6 in.) along one side of the mouth into the oropharynx. **Rationale:** *Directing the catheter along the side prevents gagging*.
- It may be necessary during oropharyngeal suctioning to apply suction to secretions that collect in the mouth and beneath the tongue.
- Remove and discard gloves.
- Perform hand hygiene.

For Nasopharyngeal and Nasotracheal Suction

- Open the lubricant.
- Open the sterile suction package.
  a. Set up the cup or container, touching only the outside.
  b. Pour sterile water or saline into the container.

Oral, Oropharyngeal, Nasopharyngeal, and Nasotracheal Suctioning—*continued*

c. Apply the sterile gloves, or apply an unsterile glove on the nondominant hand and then a sterile glove on the dominant hand. **Rationale:** *The sterile gloved hand maintains the sterility of the suction catheter, and the unsterile glove prevents the transmission of the microorganisms to the nurse*.

- With your sterile gloved hand, pick up the catheter and attach it to the suction unit. ❶

6. Test the pressure of the suction and the patency of the catheter by applying your sterile gloved finger or thumb to the port or open branch of the Y-connector (the suction control) to create suction.
- If needed, apply or increase supplemental oxygen.

7. Lubricate and introduce the catheter.
- Lubricate the catheter tip with sterile water, saline, or water-soluble lubricant. **Rationale:** *This reduces friction and eases insertion*.
- Remove oxygen with the nondominant hand, if appropriate.
- *Without applying suction*, insert the catheter into either naris and advance it along the floor of the nasal cavity. **Rationale:** *This avoids the nasal turbinates*.
- Never force the catheter against an obstruction. If one nostril is obstructed, try the other.

8. Perform suctioning.
- Apply your finger to the suction control port to start suction, and gently rotate the catheter. **Rationale:** *Gentle rotation of the catheter ensures that all surfaces are reached and prevents trauma to any one area of the respiratory mucosa due to prolonged suction*.
- Apply suction for 5 to 10 seconds while slowly withdrawing the catheter, then remove your finger from the control and remove the catheter. **Rationale:** *Intermittent suction reduces the occurrence of trauma or irritation to the trachea and nasopharynx*.
- A suction attempt should last only 10 to 15 seconds. During this time, the catheter is inserted, the suction applied and discontinued, and the catheter removed.

9. Rinse the catheter and repeat suctioning as above if necessary.
- Rinse and flush the catheter and tubing with sterile water or saline.
- Relubricate the catheter, and repeat suctioning until the air passage is clear.
- Allow sufficient time between each suction for ventilation and oxygenation. Limit suctioning to 5 minutes in total. **Rationale:** *Applying suction for too long may cause secretions to increase or may decrease the client's oxygen supply*.
- Encourage the client to breathe deeply and to cough between suctions. Use supplemental oxygen, if appropriate. **Rationale:** *Coughing and deep breathing help carry secretions from the trachea and bronchi into the pharynx, where they can be reached with the suction catheter. Deep breathing and supplemental oxygen replenish the oxygen supply that was decreased during the suctioning process*.

10. Obtain a specimen if required.
- Use a sputum trap ❷ as follows:
  a. Attach the suction catheter to the tubing of the sputum trap.
  b. Attach the suction tubing to the sputum trap air vent.
  c. Suction the client. The sputum trap will collect the mucus during suctioning.
  d. Remove the catheter from the client. Disconnect the sputum trap tubing from the suction catheter. Remove the suction tubing from the trap air vent.
  e. Connect the tubing of the sputum trap to the air vent. **Rationale:** *This retains any microorganisms in the sputum trap*.
- Connect the suction catheter to the tubing.
- Flush the catheter to remove secretions from the tubing.

11. Promote client comfort.
- Offer to assist the client with oral or nasal hygiene.
- Assist the client to a position that facilitates breathing.

12. Dispose of equipment and ensure availability for the next suction.
- Dispose of the catheter, gloves, water, and waste container.
  a. Rinse the suction tubing as needed by inserting the end of the tubing into the used water container.
  b. Wrap the catheter around your sterile gloved hand and hold the catheter as the glove is removed over it for disposal.
- Perform hand hygiene.

❶ Attaching the catheter to the suction unit.

❷ A sputum collection trap.

Continued on page 1306

Oral, Oropharyngeal, Nasopharyngeal, and Nasotracheal Suctioning—*continued*

SKILL 49.2

- Empty and rinse the suction collection container as needed or indicated by protocol. Change the suction tubing and container daily.
- Ensure that supplies are available for the next suctioning (suction kit, gloves, water or normal saline).

13. Assess the effectiveness of suctioning.

- Auscultate the client's breath sounds to ensure they are clear of secretions. Observe skin color, dyspnea, level of anxiety, and oxygen saturation levels.

14. Document relevant data.

- Record the procedure: the amount, consistency, color, and odor of sputum (e.g., foamy, white mucus; thick, green-tinged mucus; or blood-flecked mucus) and the client's respiratory status before and after the procedure. This may include lung sounds, rate and character of breathing, and oxygen saturation.
- If the procedure is carried out frequently (e.g., every hour), it may be appropriate to record only once, at the end of the shift; however, the frequency of the suctioning must be recorded.

SAMPLE DOCUMENTATION

12/12/2020 0830 Producing large amounts of thick, tenacious white mucus to back of oral pharynx but unable to expectorate into tissue. Client uses Yankauer suction tube as needed. O_2 sat increased from 89% before suctioning to 93% after suctioning. RR also decreased from 26 to 18–20 after suctioning. Lungs clear to auscultation throughout all lobes. Continuous O_2 at 2 L/min via n/c. Will continue to reassess every hour. L. Webb, RN

EVALUATION

- Conduct appropriate follow-up, such as appearance of secretions suctioned; breath sounds; respiratory rate, rhythm, and depth; pulse rate and rhythm; and skin color.
- Compare findings to previous assessment data if available.
- Report significant deviations from normal to the primary care provider.

LIFESPAN CONSIDERATIONS Suctioning

INFANTS

- A bulb syringe is used to remove secretions from an infant's nose or mouth. Care needs to be taken to avoid stimulating the gag reflex.

CHILDREN

- A catheter is used to remove secretions from an older child's mouth or nose.

OLDER ADULTS

- Older adults often have cardiac or pulmonary disease, thus increasing their susceptibility to hypoxemia related to suctioning. Watch closely for signs of hypoxemia. If noted, stop suctioning and hyperoxygenate.

duskiness, or cyanosis), restlessness, tachycardia, or decreased oxygen saturation (SpO_2) levels (also called O_2 sat) may indicate the need for suctioning. Good nursing judgment and critical thinking are necessary. Suctioning irritates mucous membranes, can increase secretions if performed too frequently, and can cause the client's oxygen saturation to drop further, put the client in bronchospasm, and if the client has a head injury, cause the intracranial pressure to increase. In other words, suctioning is based on *clinical need* versus a fixed schedule.

In addition to removing secretions that obstruct the airway and facilitating ventilation, suctioning can be performed to obtain secretions for diagnostic purposes and to prevent infection that may result from accumulated secretions.

QSEN Patient-Centered Care: Suctioning

The nurse who is providing care in the home setting for a client who requires suctioning needs to consider the following:

- Teach clients and families that the most important aspect of infection control is frequent hand washing.
- Airway suctioning in the home is considered a clean procedure.
- The catheter or Yankauer should be flushed by suctioning recently boiled or distilled water to rinse away mucus, followed by the suctioning of air through the device to dry the internal surface and, thus, discourage bacterial growth. The outer surface of the device may be wiped with alcohol or hydrogen peroxide. The suction catheter or Yankauer should be allowed to dry and then be stored in a clean, dry area.
- Suction catheters treated in the manner described above may be reused. It is recommended that catheters be discarded after 24 hours. Yankauer suction tubes may be cleaned, boiled, and reused.

Following endotracheal intubation or a tracheostomy, the trachea and surrounding respiratory tissues are irritated and react by producing excessive secretions. Sterile suctioning is necessary to remove these secretions from the trachea and bronchi to maintain a patent airway. The frequency of suctioning depends on the client's health and how recently the intubation was done. Suctioning may be necessary in clients who have

increased secretions because of pneumonia or inability to clear secretions because of altered level of consciousness. Some clients have a cough that brings secretions to the opening of the tracheostomy or endotracheal tube. They will only need suctioning at the opening of the tube and not deep suctioning.

Suctioning is associated with several complications: hypoxemia, trauma to the airway, healthcare-associated infection, and cardiac dysrhythmia, which is related to the hypoxemia. The following techniques are used to minimize or decrease these complications:

- ***Suction only as needed.*** Because suctioning the client with an ETT or tracheostomy is uncomfortable for the client and potentially hazardous because of hypoxemia, it should be performed only when indicated and *not* on a fixed schedule.
- ***Sterile technique.*** Infection of the lower respiratory tract can occur during tracheal suctioning. The nurse using sterile technique during the suctioning process can prevent this complication.
- ***No saline instillation.*** Instilling normal saline into the airway has been a common practice and a routine part of the suctioning procedure. It was thought that the saline would facilitate removal of secretions and improve the client's oxygenation status. Research, however, has shown that saline instillation does *not* facilitate removal of secretions and causes adverse effects such as hypoxemia and increased risk of pneumonia (Restrepo, Mathai, Luna, Ramirez, & Olaniyi-Adegbola, 2016).
- **Hyperinflation**. This involves giving the client breaths that are greater than the tidal volume set on the ventilator through the ventilator circuit or via a manual resuscitation bag. Three to five breaths are delivered before and after each pass of the suction catheter.
- **Hyperventilation**. This involves increasing the number of breaths the client is receiving. This can be done through the ventilator or using a manual resuscitation bag.

  Both hyperinflation and hyperventilation help prevent suction hypoxemia; however, they should be used with caution because they can cause injury as a result of overdistention of the lungs.
- **Hyperoxygenation**. This can be done with a manual resuscitation bag or through the ventilator and is performed by increasing the oxygen flow (usually to 100%) before suctioning and between suction attempts. This is the best technique to avoid suction-related hypoxemia.
- ***Safe catheter size.*** To prevent hypoxia when tracheostomy and endotracheal suctioning are administered, the outer diameter of the suction catheter should not exceed one-half the internal diameter of the artificial airway. A formula to determine suction catheter size is to multiply the artificial airway's diameter times 2. For example, an artificial airway (e.g., tracheostomy) diameter of 8 mm $\times$ 2 = 16. A size 16 French suction catheter would be safe to use (Smith et al., 2017, p. 1207).

The nurse uses sterile techniques to prevent infection of the respiratory tract (Skill 49.3). The traditional method of suctioning an ETT or tracheostomy is sometimes referred to as the *open suction system*. If a client is connected to a ventilator, the nurse disconnects the client from the ventilator, suctions the airway, reconnects the client to the ventilator, and discards the suction catheter. Other drawbacks to the open suction system include the nurse needing to wear personal protective equipment (e.g., goggles or face shield, gown) to avoid exposure to the client's sputum and the potential cost of one-time catheter use, especially if the client requires frequent suctioning.

With the *closed suction system* (Figure 49.28 ■), the suction catheter attaches to the ventilator tubing and the client does not need to be disconnected from the ventilator. The nurse is not exposed to any secretions because the suction catheter is enclosed in a plastic sheath. The catheter can be reused as many times as

Figure 49.28 ■ A closed suction system.

necessary until the system is changed. The nurse needs to inquire about the agency's policy for changing the closed suction system.

QSEN Patient-Centered Care: Suctioning a Tracheostomy or Endotracheal Tube

In the home care setting, the nurse needs to consider the following for clients requiring suctioning of a tracheostomy or endotracheal tube:

- Whenever possible, the client should be encouraged to clear the airway by coughing.
- Clients may need to learn to suction their secretions if they cannot cough effectively.
- Clean gloves should be used when endotracheal suctioning is performed in the home environment.
- The nurse needs to instruct the caregiver on how to determine the need for suctioning and the correct process and rationale underlying the practice of suctioning to avoid potential complications of suctioning.
- Stress the importance of adequate hydration as it thins secretions, which can aid in the removal of secretions by coughing or suctioning.

Suctioning a Tracheostomy or Endotracheal Tube

SKILL 49.3

PURPOSES

- To maintain a patent airway and prevent airway obstructions
- To promote respiratory function (optimal exchange of oxygen and carbon dioxide into and out of the lungs)
- To prevent pneumonia that may result from accumulated secretions

ASSESSMENT

Assess the client for the presence of adventitious (abnormal) breath sounds. Assess the client's cough reflex and note the client's ability or inability to remove the secretions by coughing.

PLANNING

Assignment

Suctioning a tracheostomy or endotracheal tube is a sterile, invasive technique requiring application of scientific knowledge and problem-solving. This skill is performed by a nurse or respiratory therapist and is not assigned to AP.

Equipment

- Resuscitation bag (bag valve mask) connected to 100% oxygen
- Sterile towel (optional)
- Equipment for suctioning (see Skill 49.2)
- Goggles and mask (if necessary)
- Gown (if necessary)
- Sterile gloves
- Moisture-resistant bag

IMPLEMENTATION

Preparation

Determine if the client has been suctioned previously and, if so, review the documentation of the procedure. This information can be very helpful in preparing the nurse for both the physiologic and psychologic impact of suctioning on the client.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how to participate. Inform the client that suctioning usually causes some intermittent coughing and that this assists in removing the secretions.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Prepare the client.
   - If not contraindicated, place the client in the semi-Fowler's position to promote deep breathing, maximum lung expansion, and productive coughing. **Rationale:** *Deep breathing oxygenates the lungs, counteracts the hypoxic effects of suctioning, and may induce coughing. Coughing helps to loosen and move secretions*.
5. Prepare the equipment for an open suction system—see *Variation* section for a closed suction system.
   - Attach the resuscitation apparatus to the oxygen source. ❶ Adjust the oxygen flow to 100%.

❶ Attaching the resuscitation apparatus to the oxygen source.

   - Open the sterile supplies:
     a. Suction kit or catheter
     b. Sterile basin or container.

Suctioning a Tracheostomy or Endotracheal Tube—*continued*

- Pour sterile normal saline or water into sterile basin or container.
- Place the sterile towel, if used, across the client's chest below the tracheostomy or on a workspace.
- Turn on the suction, and set the pressure in accordance with agency policy. The suction pressure should be set at what is needed to adequately remove secretions. The recommended suction pressure for the open suction system is 100–120 mm Hg vacuum (Smith et al., 2017, p. 1207).
- Apply goggles, mask, and gown if necessary.
- Apply sterile gloves. Some agencies recommend putting a sterile glove on the dominant hand and an unsterile glove on the nondominant hand. **Rationale:** *The sterile gloved hand maintains the sterility of the suction catheter, and the unsterile glove holds the suction connecting tubing and prevents transmission of the microorganisms to the nurse*.
- Holding the catheter in the dominant hand and the connector in the nondominant hand, attach the suction catheter to the suction tubing (see Figure ❶ in Skill 49.2).

6. Flush and lubricate the catheter.
- Using the dominant hand, place the catheter tip in the sterile saline solution.
- Using the thumb of the nondominant hand, occlude the thumb control and suction a small amount of the sterile solution through the catheter. **Rationale:** *This determines that the suction equipment is working properly and lubricates the outside and the lumen of the catheter. Lubrication eases insertion and reduces tissue trauma during insertion. Lubricating the lumen also helps prevent secretions from sticking to the inside of the catheter*.

7. If the client does not have copious secretions, hyperventilate the lungs with a resuscitation bag before suctioning.
- Summon an assistant, if one is available, for this step.
- Using your nondominant hand, turn on the oxygen to 12 to 15 L/min.
- If the client is receiving oxygen, disconnect the oxygen source from the tracheostomy tube using your nondominant hand.
- Attach the resuscitator to the tracheostomy or ETT. ❷
- Compress the resuscitation bag three to five times, as the client inhales. This is best done by a second staff member who can use both hands to compress the bag.
- Observe the rise and fall of the client's chest to assess the adequacy of each ventilation.
- Remove the resuscitation device and place it on the bed or the client's chest with the connector facing up.

❷ Attaching the resuscitator to the tracheostomy tube.

Variation: Using a Ventilator to Provide Hyperventilation
If the client is on a ventilator, use the ventilator for hyperventilation and hyperoxygenation. Newer models have a mode that provides 100% oxygen for 2 minutes and then switches back to the previous oxygen setting as well as a manual breath or sigh button. **Rationale:** *The use of ventilator settings provides more consistent delivery of oxygenation and hyperinflation than a resuscitation device*.

8. If the client has copious secretions, do not hyperventilate with a resuscitator. *Instead:*
- Keep the regular oxygen delivery device on and increase the liter flow or adjust the FiO_2 to 100% for several breaths before suctioning. **Rationale:** *Hyperventilating a client who has copious secretions can force the secretions deeper into the respiratory tract*.

9. Quickly but gently insert the catheter *without* applying any suction.
- With your nondominant thumb off the suction port, quickly but gently insert the catheter into the trachea through the tracheostomy tube. ❸ **Rationale:** *To prevent tissue trauma and oxygen loss, suction is not applied during insertion of the catheter*.
- Insert the catheter about 1 to 2 cm (1/2 to 1 in.) past the distal end of the tube until resistance is felt, even if the client coughs (Smith et al., 2017, p. 1208).

10. Perform suctioning.
- Apply suction for 5 to 10 seconds by placing the nondominant thumb over the thumb port. **Rationale:** *Suction time is restricted to 10 seconds or less to minimize oxygen loss*.
- Rotate the catheter by rolling it between your thumb and forefinger while slowly withdrawing it. **Rationale:** *This prevents tissue trauma by minimizing the suction time against any part of the trachea*.
- Withdraw the catheter completely, and release the suction.
- Hyperventilate the client.
- Suction again, if needed.

11. Reassess the client's oxygenation status and repeat suctioning.
- Observe the client's respirations and skin color. Check the client's pulse if necessary, using your nondominant hand. If the client is on a cardiac monitor, assess the rate and rhythm.
- Encourage the client to breathe deeply and to cough between suctions.

❸ Inserting the catheter into the trachea through the tracheostomy tube. *Note:* Suction is not applied while inserting the catheter.

Continued on page 1310

Suctioning a Tracheostomy or Endotracheal Tube—*continued*

SKILL 49.3

- Allow 2 to 3 minutes with oxygen, as appropriate between suctions when possible. **Rationale:** *This provides an opportunity for reoxygenation of the lungs*.
- Flush the catheter and repeat suctioning until the air passage is clear and the breathing is relatively effortless and quiet.
- After each suction, pick up the resuscitation bag with your nondominant hand and ventilate the client with no more than three breaths.

12. Dispose of equipment and ensure availability for the next suction.
- Flush the catheter and suction tubing.
- Turn off the suction and disconnect the catheter from the suction tubing.
- Wrap the catheter around your sterile hand and peel the glove off so that it turns inside out over the catheter. Remove the other glove.
- Discard the gloves and the catheter in the moisture-resistant bag.
- Perform hand hygiene.
- Replenish the sterile fluid and supplies so that the suction is ready for use again. **Rationale:** *Clients who require suctioning often require it quickly, so it is essential to leave the equipment at the bedside ready for use*.
- Be sure that the ventilator and oxygen settings are returned to presuctioning settings. **Rationale:** *On some ventilators this is automatic, but always check. It is very dangerous for clients to be left on 100% oxygen*.

13. Provide for client comfort and safety.
- Assist the client to a comfortable, safe position that aids breathing. If the client is conscious, a semi-Fowler's position is frequently indicated. If the client is unconscious, Sims' position aids in the drainage of secretions from the mouth.

14. Document relevant data.
- Record the suctioning, including the amount and description of suction returns and any other relevant assessments.

Variation: Closed Suction System

- If a catheter is not already attached, apply clean gloves, aseptically open a new closed suction system catheter set, and attach the ventilator connection on the T piece to the ventilator tubing. Attach the client connection to the ETT or tracheostomy.
- Attach one end of the suction connecting tubing to the suction connection port of the closed system and the other end of the connecting tubing to the suction device.
- Turn suction on, occlude or kink tubing, and depress the suction control valve (on the closed catheter system) to set suction to the appropriate level. Release the suction control valve.
- Use the ventilator to hyperoxygenate and hyperinflate the client's lungs.
- Unlock the suction control mechanism if required by the manufacturer.
- Advance the suction catheter enclosed in its plastic sheath with the dominant hand. Steady the T piece with the nondominant hand.
- Depress the suction control valve and apply continuous suction for no more than 10 seconds and gently withdraw the catheter.
- Repeat as needed remembering to provide hyperoxygenation and hyperinflation as needed.
- When suctioning is completed, withdraw the catheter into its sleeve and close the access valve, if appropriate. **Rationale:** *If the system does not have an access valve on the client connector, the nurse needs to observe for the potential of the catheter migrating into and partially obstructing the artificial airway*.
- Flush the catheter by instilling normal saline into the irrigation port and applying suction. Repeat until the catheter is clear.
- Close the irrigation port and close the suction valve.
- Remove and discard gloves.
- Perform hand hygiene.

SAMPLE DOCUMENTATION

12/13/2020 1000 Coarse crackles in RLL and LLL. Requires suctioning about every 1–2 h. Obtained large amount of pinkish-tinged, white thin mucus via ETT. Breath sounds clearer after suctioning. SpO_2 increased from 90% before suctioning to 95% after suctioning. Client signals when he wants to be suctioned. C. Holmes, RN

EVALUATION

- Perform a follow-up examination of the client to determine the effectiveness of the suctioning (e.g., respiratory rate, depth, and character; breath sounds; color of skin and nail beds; character and amount of secretions suctioned; changes in vital signs [e.g., heart rate, oxygen saturation]).
- Compare findings to previous assessment data if available.
- Report significant deviations from normal to the primary care provider.

LIFESPAN CONSIDERATIONS Suctioning a Tracheostomy or Endotracheal Tube

INFANTS AND CHILDREN

- Have an assistant gently restrain the child to keep the child's hands out of the way. The assistant should maintain the child's head in the midline position.

OLDER ADULTS

- Healthcare-associated pneumonia and ventilator-associated pneumonia (VAP) can occur because of infected secretions in the upper airway. Oral antiseptic rinses (e.g., chlorhexidine gluconate) reduce the rate of healthcare-associated pneumonia in critically ill clients ("Prevention," 2017).
- Do a thorough lung assessment before and after suctioning to determine effectiveness of suctioning and to be aware of any special problems.

SKILL 49.4

Providing Tracheostomy Care

PURPOSES

- To maintain airway patency
- To maintain cleanliness and prevent infection at the tracheostomy site
- To facilitate healing and prevent skin excoriation around the tracheostomy incision
- To promote comfort

ASSESSMENT

Assess

- Respiratory status including ease of breathing, rate, rhythm, depth, lung sounds, and oxygen saturation level
- Pulse rate
- Character and amount of secretions from tracheostomy site
- Presence of drainage on tracheostomy dressing or ties
- Appearance of incision (note any redness, swelling, purulent discharge, or odor)

PLANNING

Assignment

Tracheostomy care involves application of scientific knowledge, sterile technique, and problem-solving, and therefore needs to be performed by a nurse or respiratory therapist.

Equipment

- Sterile disposable tracheostomy cleaning kit or supplies including sterile containers, sterile nylon brush or pipe cleaners, sterile applicators, gauze squares
- Disposable inner cannula if applicable
- Towel or drape to protect bed linens
- Sterile suction catheter kit (suction catheter and sterile container for solution)
- Sterile normal saline (Some agencies may use a mixture of hydrogen peroxide and sterile normal saline. Check agency protocol for soaking solution.)
- Sterile gloves (two pairs—one pair is for suctioning if needed)
- Clean gloves
- Moisture-proof bag
- Commercially prepared sterile tracheostomy dressing or sterile 4×4 gauze dressing
- Cotton twill ties or Velcro collar
- Clean scissors

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how to participate. Provide for a means of communication, such as eye blinking or raising a finger, to indicate pain or distress. Follow through by carefully observing the client throughout the procedure, and offering periodic eye contact, caring touch, and verbal reassurance.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Prepare the client and the equipment.
   - Assist the client to a semi-Fowler's or Fowler's position *to promote lung expansion*.
   - Suction the tracheostomy tube, if needed. (See Skill 49.3.)
   - If suctioning was required, allow the client to rest and restore oxygenation.
   - Open the tracheostomy kit or sterile basins.
   - Establish a sterile field.
   - Open other sterile supplies as needed including sterile applicators, suction kit, tracheostomy dressing, and disposable inner cannula, if applicable.
   - Pour the soaking solution and sterile normal saline into separate containers.
   - Apply clean gloves.
   - Remove the oxygen source.
   - Unlock the inner cannula (if present) and remove it by gently pulling it out toward you in line with its curvature. Place the inner cannula in the soaking solution, if not a disposable inner cannula. **Rationale:** *This moistens and loosens dried secretions*.
   - Based on the client's respiratory assessments, place oxygen source over or near the outer cannula. **Rationale:** *This prevents oxygen desaturation by maintaining oxygen to the client*.
   - Remove the soiled tracheostomy dressing. Place the soiled dressing in your gloved hand and peel the glove off so that it turns inside out over the dressing. Remove and discard the gloves and the dressing.
   - Perform hand hygiene.
   - Apply sterile gloves. Keep your dominant hand sterile during the procedure.
5. Clean the inner cannula. (See the *Variation* section for using a disposable inner cannula.)
   - Remove the inner cannula from the soaking solution.
   - Clean the lumen and entire inner cannula thoroughly using the brush or pipe cleaners moistened with sterile normal saline. ❶ Inspect the cannula for cleanliness by holding it at eye level and looking through it into the light.
   - Rinse the inner cannula thoroughly in the sterile normal saline.
   - After rinsing, gently tap the cannula against the inside edge of the sterile saline container. Use a pipe cleaner folded in half to dry only the inside of the cannula; do not dry the outside. **Rationale:** *This removes excess liquid from the cannula and prevents possible aspiration by the client, while leaving a film of moisture on the outer surface to lubricate the cannula for reinsertion*.
6. Replace the inner cannula, securing it in place.
   - Insert the inner cannula by grasping the outer flange and inserting the cannula in the direction of its curvature.
   - Lock the cannula in place by turning the lock (if present) into position to secure the flange of the inner cannula to the outer cannula.

Continued on page 1312

SKILL 49.4

Providing Tracheostomy Care—*continued*

1 Cleaning the inner cannula with a brush.

3 A commercially prepared tracheostomy dressing of nonraveling material.

7. Clean the incision site and tube flange.
- Using sterile applicators or gauze dressings moistened with normal saline, clean the incision site. 2 Handle the sterile supplies with your dominant hand. Use each applicator or gauze dressing only once and then discard. **Rationale:** *This avoids contaminating a clean area with a soiled gauze dressing or applicator*.
- Hydrogen peroxide may be used (usually in a half-strength solution mixed with sterile normal saline; use a separate sterile container if this is necessary) to remove crusty secretions around the tracheostomy site. Do not use directly on the site. Check agency policy. Thoroughly rinse the cleaned area using gauze squares moistened with sterile normal saline. **Rationale:** *Hydrogen peroxide can be irritating to the skin and inhibit healing if not thoroughly removed*.
- Clean the flange of the tube in the same manner.
- Thoroughly dry the client's skin and tube flanges with dry gauze squares.

8. Apply a sterile dressing.
- Use a commercially prepared split-gauze tracheostomy dressing of nonraveling material. 3 Never use cotton-filled gauze squares or cut the 4×4 gauze. **Rationale:** *Cotton lint or gauze fibers can be aspirated by the client, potentially creating a tracheal abscess*. Newer products include a nonadhesive hydrocellular dressing, which is a cushioned pad that absorbs large amounts of secretions.
- Place the dressing under the flange of the tracheostomy tube.
- While applying the dressing, ensure that the tracheostomy tube is securely supported. **Rationale:** *Excessive movement of the tracheostomy tube irritates the trachea*.

9. Change the tracheostomy ties or Velcro collar.
- Change as needed to keep the skin clean and dry.
- Twill tape and specially manufactured Velcro ties are available. Twill tape is inexpensive and readily available; however, it is easily soiled and can trap moisture, which leads to irritation of the skin of the neck. Velcro ties are becoming more commonly used. 4 They are wider, are more comfortable, and cause less skin abrasion.
- For client safety, the literature recommends a two-person technique when changing the securing device to prevent tube dislodgement. This involves one staff member holding the tracheostomy tube in place while the other changes the securing device.

Two-Strip Method (Twill Tape)
- Cut two unequal strips of twill tape, one approximately 25 cm (10 in.) long and the other about 50 cm (20 in.) long. **Rationale:** *Cutting one tape longer than the other allows them to be fastened at the side of the neck for easy access and to avoid the pressure of a knot on the skin at the back of the neck*.

2 Using an applicator stick to clean the tracheostomy site.

4 A Velcro tracheostomy tie.

Providing Tracheostomy Care—*continued*

- Cut a 1-cm (0.5-in.) lengthwise slit approximately 2.5 cm (1 in.) from one end of each strip. To do this, fold the end of the tape back onto itself about 2.5 cm (1 in.), then cut a slit in the middle of the tape from its folded edge.
- Leaving the old ties in place, thread the slit end of one clean tape through the eye of the tracheostomy flange from the bottom side; then thread the long end of the tape through the slit, pulling it tight until it is securely fastened to the flange. **Rationale:** *Leaving the old ties in place while securing the clean ties prevents inadvertent dislodging of the tracheostomy tube. Securing tapes in this manner avoids the use of knots, which can come untied or cause pressure and irritation*.
- If old ties are very soiled or it is difficult to thread new ties onto the tracheostomy flange with old ties in place, have an assistant apply a sterile glove and hold the tracheostomy in place while you replace the ties. **Rationale:** *This is very important because movement of the tube during this procedure may cause irritation and stimulate coughing. Coughing can dislodge the tube if the ties are undone*.
- Repeat the process for the second tie.
- Ask the client to flex the neck. Slip the longer tape under the client's neck, place a finger between the tape and the client's neck, (5) and tie the tapes together at the side of the neck. **Rationale:** *Flexing the neck increases its circumference the way coughing does. Placing a finger under the tie prevents making the tie too tight, which could interfere with coughing or place pressure on the jugular veins*.
- Tie the ends of the tapes using square knots. Cut off any long ends, leaving approximately 1 to 2 cm (0.5 in.). **Rationale:** *Square knots prevent slippage and loosening. Adequate ends beyond the knot prevent the knot from inadvertently untying*.
- Once the clean ties are secured, remove the soiled ties and discard.

One-Strip Method (Twill Tape)

- Cut a length of twill tape 2.5 times the length needed to go around the client's neck from one tube flange to the other.

(5) Placing a finger underneath the tie tape before tying it.

- Thread one end of the tape into the slot on one side of the flange.
- Bring both ends of the tape together. Take them around the client's neck, keeping them flat and untwisted.
- Thread the end of the tape next to the client's neck through the slot from the back to the front.
- Have the client flex the neck. Tie the loose ends with a square knot at the side of the client's neck, allowing for slack by placing one finger under the ties as with the two-strip method. Cut off long ends.
- Tape and pad the tie knot.
- Place a folded 4×4 gauze square under the tie knot, and apply tape over the knot. **Rationale:** *This reduces skin irritation from the knot and prevents confusing the knot with the client's gown ties*.
- Check the tightness of the ties.
- Frequently check the tightness of the tracheostomy ties and position of the tracheostomy tube. **Rationale:** *Swelling of the neck may cause the ties to become too tight, interfering with coughing and circulation. Ties can loosen in restless clients, allowing the tracheostomy tube to extrude from the stoma*.

Velcro Collar Method

- Thread one piece of the collar with the Velcro end into the slot on one side of the flange.
- Take the collar around the back of the client's neck, keeping it flat.
- Thread the other piece of the collar with the Velcro end into the slot on the other side of the flange.
- Take the second piece of the collar around the back of the client's neck, keeping it flat.
- Have the client flex the neck and secure the two pieces of the collar together with the Velcro, allowing space for one to two fingers between the collar and the client's neck.
- Check the tightness of the collar as with the tie method.

10. Remove and discard sterile gloves.
- Perform hand hygiene.

11. Document all relevant information.
- Record suctioning, tracheostomy care, and the dressing change, noting your assessments.

Variation: Using a Disposable Inner Cannula

- Check policy for frequency of changing inner cannula because standards vary among institutions.
- Open a new cannula package.
- Using a gloved hand, unlock the current inner cannula (if present) and remove it by gently pulling it out toward you in line with its curvature.
- Check the cannula for amount and type of secretions and discard properly.
- Pick up the new inner cannula touching only the outer locking portion.
- Insert the new inner cannula into the tracheostomy.
- Lock the cannula in place by turning the lock (if present) or clipping in place.

SAMPLE DOCUMENTATION

12/11/2020 0900 Respirations 18–20/min. Lung sounds clear. Able to cough up secretions requiring little suctioning. Inner cannula changed. Trach dressing changed. Minimal amount of serosanguineous drainage present. Trach incision area pink to reddish in color 0.2 cm around entire opening. No broken skin noted in the reddened area. J. Garcia, RN

Providing Tracheostomy Care—*continued*

SKILL 49.4

EVALUATION

- Perform appropriate follow-up such as determining character and amount of secretions, drainage from the tracheostomy, appearance of the tracheostomy incision, pulse rate and respiratory status compared to baseline data, and complaints of pain or discomfort at the tracheostomy site.
- Compare findings to previous assessment data if available.
- Report significant deviations from normal to the primary care provider.

QSEN Patient-Centered Care: Tracheostomy Care

In the home care setting, the nurse needs to consider the following for clients requiring tracheostomy care:

- For tracheostomies older than 1 month, clean technique (rather than sterile technique) is used for tracheostomy care.
- Stress the importance of good hand hygiene to the caregiver.
- Tap water may be used for rinsing the inner cannula.
- Teach the caregiver the tracheostomy care procedure and observe a return demonstration. Periodically reassess caregiver knowledge and tracheostomy care technique.
- Inform the caregiver of the signs and symptoms that may indicate an infection of the stoma site or lower airway.
- Names and telephone numbers of healthcare personnel who can be reached for emergencies or advice must be available to the client or caregiver.
- If the tracheostomy is permanent, provide contact information for available support groups.

LIFESPAN CONSIDERATIONS Tracheostomy Care

INFANTS AND CHILDREN

- An assistant should always be present while tracheostomy care is performed.
- Always keep a sterile, packaged tracheostomy tube taped to the child's bed so that if the tube dislodges, a new one is available for immediate reintubation.

OLDER ADULTS

- Older adult skin is fragile and prone to breakdown. Care of the skin at the tracheostomy stoma is very important.

EVIDENCE-BASED PRACTICE

Evidence-Based Practice

How Important Is Communication to a Client with a Tracheostomy?

It is unknown how many tracheostomies are performed each year; however, this procedure has become common practice. Few studies have explored the communication experience of tracheostomy clients in the intensive care unit (ICU). As a result, Tolotti et al. (2018) conducted a study to explore the actual experiences of adult clients with tracheostomies, who were not under sedation or mechanically ventilated, in their communication with nurses during their stay in the ICU. The researchers used interpretive phenomenology methodology to gain a deeper understanding of the clients' subjective experiences when they communicated with nurses. The methods for data collection included: (1) Observation during the clients' stay in the ICU. Observational data were used to gain a better understanding of the problems the clients reported in their interviews and during data analysis to provide a clearer context in which the communication occurred. (2) In-depth interviews with the clients after they left the ICU. The purpose was to explore the communication difficulties experienced by the clients during their communication experience with the nurses and to identify what facilitated and hindered their communication. The researchers asked the clients which nurses they particularly remembered. (3) Interviews with the nurses whom the clients remembered best in relation to their communication experiences. The study included a total of eight clients. Between three and five participant observations were conducted per client. Seven interviews were conducted with the nurses.

The data analysis resulted in two themes to the actual experience of communication, four factors relating to discomfort during communication and three to comfort. The first theme was *feeling powerless and frustrated*. The clients found it difficult to communicate, which was frustrating, and not being able to speak caused a feeling of powerlessness. As one client stated, "not being able to speak blocked all other human activities." The second theme was *facing continual misunderstanding, resignation, and anger*. The clients tried to use different strategies such as saying words softly, using their eyes, and moving their head. Communication boards required a lot of concentration and attention and often clients were too weak to write legibly. Clients took for granted that the nurses would be able to understand them. When this did not happen, the clients developed feelings of anger or resignation and they just gave up trying to communicate.

The four sources of discomfort included: (1) *Struggling with not knowing what is happening*. The clients often reported they were not aware of their clinical condition and the therapeutic decisions. Some did not remember receiving any information, whereas others reported that the reason they did not receive information was due to the lack of time or because the nurses had other more urgent situations. (2) *Feeling as if other people have given up on me*. Because of the difficulty in communicating and perceiving that there was little hope that their condition would improve, some clients gave up. What gave strength to some of the clients to not give up was the presence of their loved ones. (3) *Living in isolation*. Not being able to speak made it difficult to interact with others, causing a sense of isolation that was linked to a feeling of worthlessness. Sleeping was a way of reducing this suffering, and clients became angry when their sleep was interrupted. (4) *Feeling invisible*. The clients reported that because they could not speak and relate to others they were not involved in the care plan and felt as though they did not exist. Some did not like it when the physicians would not speak directly to them but only to the nurses. Clients felt that decisions were being made and they were not informed or involved in the process.

The three sources of comfort included: (1) *Comforted by being with significant people*. The presence of family was very important and was a source of comfort, encouragement, hope, and protection. The family members also acted as intermediaries as they helped the nurses understand what the clients needed. (2) *Reassured by having my call bell nearby*. Having a safe and quick way to call for help was a source of great reassurance. (3) *Feeling comforted by the nurses' presence*. The clients acknowledged the nurses' specialized competence and their trustworthiness. They were comforted when the nurses showed interest in them, which they perceived through the nurses' gestures, words, smiles, and time they spent with them.

The study also analyzed those themes that were similar and different for both the clients and the nurses. *Frustration because of difficulty with communication* occurred among both groups. The anger and frustration reported by the clients was also reported by the nurses. The nurses reported that repeatedly having to say "I don't understand" was very difficult and sometimes led them to use avoidance strategies such as doing other things. The *comfort factors* for both groups included the presence of caring, as expressed previously by the clients. The nurses reported that showing that they cared for the clients was important to them. Another important comfort factor for both was the presence of family members. Some nurses, however, were ambivalent about the presence of family members. While they recognized the importance for the clients, the family members were sometimes perceived as causing interference with the nurse's work. The *discomfort factors* for both included the lack of information, as previously reported by the clients. For nurses, the information problems were due mainly to communication difficulties; that is, not being able to easily talk with the client could impact the ability to provide correct and complete information. The nurses also reported a feeling of isolation. Specifically, they were not able to provide the amount of one-on-one time that they desired with the clients because there was not enough time.

Implications

Communication is a key element of an effective and therapeutic nurse-client relationship. This study reflected the importance of communication for tracheostomy clients and showed how communication is linked to many aspects of the client's experience. The results of this study can help nurses to become aware of tracheostomy clients' sources of comfort and discomfort during communication with nurses and to use strategies to reduce tracheostomy clients' feelings of frustration and powerlessness due to their inability to use their voice.

Chest Tubes and Drainage Systems

If the thin, double-layered pleural membrane is disrupted by lung disease, surgery, or trauma, the negative pressure between the pleural layers may be lost. The lung then collapses because it is no longer drawn outward as the diaphragm and intercostal muscles contract during inhalation. When air collects in the pleural space, it is known as a **pneumothorax**. A **hemothorax** is the accumulation of blood in the pleural space, and a **pleural effusion** exists when there is excessive fluid in the pleural space. The air, blood, or fluid in the pleural space places pressure on lung tissue and interferes with lung expansion. Chest tubes may be inserted into the pleural cavity to restore negative pressure and drain collected fluid or blood. Because air rises, chest tubes for pneumothorax often are placed in the upper anterior thorax, whereas chest tubes used to drain blood and fluid generally are placed in the lower lateral chest wall.

When chest tubes are inserted, they must be connected to a sealed drainage system or a one-way valve that allows air and fluid to be removed from the chest cavity but prevents air from entering from the outside. Sterile disposable drainage systems are used to prevent outside air from entering the chest tube. These systems typically have a suction control chamber, a water-seal chamber, and a closed collection chamber, for drainage (Figure 49.29 ■). With the water-seal system, when the client inhales, the water prevents air from entering the system from the

Figure 49.29 ■ A disposable chest drainage system.

atmosphere. During exhalation, however, air can exit the chest cavity, bubbling up through the water. Suction can be added to the system to facilitate removing air and secretions from the chest cavity. The drainage system should always be kept below the level of the client's chest to prevent fluid and drainage from being drawn back into the chest cavity.

A Heimlich valve may be used for ambulatory clients (Figure 49.30 ■). The Heimlich valve is a one-way flutter valve that allows air to escape from the chest cavity, but prevents air from reentering. The arrow on the cover of the valve should always point away from the client. At each assessment, observe the inner valve carefully for movement during exhalation, indicating airflow through the device. The Heimlich valve is not designed to collect fluid. Another device, attached to the chest tube and called the Pneumostat, also has a one-way valve and, unlike the Heimlich valve, a small built-in collection chamber. It is used exclusively for clients with a pneumothorax who usually have small amounts of fluid (Figure 49.31 ■).

Nursing responsibilities regarding drainage systems include the following:

- Monitor and maintain the patency and integrity of the drainage system.
- Assess the client's vital signs, oxygen saturation, cardiovascular status, and respiratory status. Check the breath sounds bilaterally and check for symmetry of breath sounds.
- Observe the dressing site at least every 4 hours. Inspect the dressing for excessive and abnormal drainage, such as bleeding or foul-smelling discharge. Palpate around the dressing site, and listen for a crackling sound indicative of subcutaneous emphysema. *Subcutaneous emphysema, which is air in the subcutaneous tissues, can result from a poor seal at the chest tube insertion site.*
- Determine level of discomfort with and without activity and medicate the client for pain if indicated.
- Encourage deep-breathing exercises and coughing every 2 hours (this may be contraindicated in clients who have had a lung removed). Have the client sit upright to perform the exercises, and splint the chest around the tube insertion site with a pillow or with a hand to minimize discomfort.
- Reposition the client every 2 hours. When the client is lying on the affected side, place rolled towels beside the tubing. *Frequent position changes promote drainage, prevent complications, and provide comfort. Rolled towels prevent occlusion of the chest tube by the client's weight.*
- Assist the client with range-of-motion exercises of the affected shoulder three times per day to maintain joint mobility.
- Ensure that the connections are securely taped and that the chest tube is secured to the client's chest wall.
- Keep the collection device below the client's chest level.
- Frequently check the water-seal and suction control chambers. The water can evaporate and water may need to be added to the chamber. The water-seal level should fluctuate with respiratory effort.
- Assess the drainage in the tubing and collection chamber. The drainage is measured at regularly scheduled times (check agency policy). Mark the date and time at the fluid level on the drainage chamber. The unit is not replaced until almost full.
- Avoid aggressive chest tube manipulation (e.g., milking or stripping the tube). Milking requires a healthcare provider's order. Stripping is no longer considered an acceptable practice (Smith et al., 2017, p. 1217).
- Avoid clamping the chest tube because this increases the risk of a tension pneumothorax. You can clamp the tube for a moment to replace the drainage unit or to locate the source of an air leak, but never when transporting a client or for any extended period of time.

Figure 49.30 ■ Heimlich chest drain valve.

Figure 49.31 ■ The Pneumostat is an example of a device often used for clients with a pneumothorax. It has a one-way valve and a small collection chamber.

- If the tube becomes disconnected from the collecting system, submerge the end in 2.5 cm (1 in.) of sterile saline or water *to maintain the seal*. If the chest tube is inadvertently pulled out, the wound should be immediately covered with a dry sterile dressing. If you can hear air leaking out of the site, ensure that the dressing is not occlusive. *If the air cannot escape, this would lead to a tension pneumothorax. A tension pneumothorax occurs when there is buildup of air in the pleural space and it cannot escape, causing increased pressure. This pressure can eventually compromise cardiovascular function*.
- When transporting and ambulating the client:
  a. Keep the water-seal unit below chest level and upright.
  b. Disconnect the drainage system from the suction apparatus before moving the client and make sure the air vent is open.
- Use standard precautions and personal protective equipment while manipulating the system and assisting with insertion or removal.

Chest tube insertion and removal require sterile technique and must be done without introducing air or microorganisms into the pleural cavity. Removal of a chest tube is a brief but quite painful procedure. Medicate the client before the removal. Remove the dressing around the tube and prepare the dressing that will cover the insertion site. This will be an occlusive dressing if there is no purse-string suture around the insertion site to prevent air from entering the chest. Generally, the healthcare provider performs the removal but, in some areas, specially trained nurses may be permitted to do so.

Evaluating

Using the goals and desired outcomes identified in the planning stage of the nursing process, the nurse collects data to evaluate the effectiveness of interventions. If outcomes are not achieved, the nurse, client, and support person if appropriate need to explore the reasons before modifying the care plan. For example, if the outcome "Respirations unlabored and rate is within expected range" is not met, examples of questions that need to be considered include the following:

- What is the client's perception of the problem?
- Is the client complaining of shortness of breath or difficulty breathing?
- Is the client taking medications or performing treatments such as percussion, vibration, and postural drainage as prescribed?
- Has the client been exposed to an upper respiratory infection that is affecting breathing?
- Do other factors need to be considered, such as the client's psychologic stress level?

Examples of questions to consider if the outcome "Able to complete ADLs without fatigue" is not met include the following:

- What other factors may be affecting the client's ability to complete ADLs?
- Is the client getting adequate sleep? If not, what is interfering with the client's rest?
- Are there assistive devices (e.g., a shower chair, clothing that is easy to put on) that could help the client achieve this goal?
- Does the client need help with housework and other ADLs?
- Is the client's diet adequate to meet nutritional needs?

NURSING CARE PLAN **Altered Respiratory Status**

ASSESSMENT DATA	NURSING DIAGNOSIS	DESIRED OUTCOMES*
NURSING ASSESSMENT Julie Singh, a 39-year-old secretary, was admitted to the hospital with an elevated temperature; fatigue; rapid, labored respirations; and mild dehydration. The nursing history reveals that she has had a "bad cold" for several weeks that just wouldn't go away. She has been dieting for several months and skipping meals. Ms. Singh mentions that in addition to her full-time job as a secretary she is attending college classes two evenings a week. She has smoked one package of cigarettes per day since she was 18 years old. Chest x-ray confirms pneumonia. **Physical Examination** Height: 167.6 cm (5′6″) Weight: 54.4 kg (120 lb) Temperature: 39.4°C (103°F) Pulse: 68 beats/min **Diagnostic Data** Chest x-ray: right lobar infiltration WBC: 14,000 pH: 7.49	Altered respiratory status related to thick sputum, secondary to pneumonia (as evidenced by rapid respirations, diminished and adventitious breath sounds, thick yellow sputum)	**Respiratory Status: Airway Patency [0410]** as evidenced by: • No deviation from normal range for respiratory rate • No accumulation of sputum • No adventitious breath sounds

Continued on page 1318

NURSING CARE PLAN Altered Respiratory Status—*continued*

Respirations: 24/min	$PaCO_2$: 33 mmHg
Blood pressure: 118/70 mmHg	HCO_3^-: 20 mEq/L
Skin pale; cheeks flushed	PaO_2: 80 mmHg
Chills; use of accessory muscles; inspiratory crackles with diminished breath sounds right base; expectorating thick, yellow sputum	O_2 sat: 88%

NURSING INTERVENTIONS*/SELECTED ACTIVITIES	RATIONALE
COUGH ENHANCEMENT [3250]	
Assist Ms. Singh to a sitting position with head slightly flexed, shoulders relaxed, and knees flexed.	*Lying flat causes the abdominal organs to shift toward the chest, crowding the lungs and making it more difficult to breathe.*
Encourage her to take several deep breaths.	*Deep breathing promotes oxygenation before controlled coughing.*
Encourage her to take a deep breath, hold for 2 seconds, and cough two or three times in succession.	*Controlled coughing is accomplished by closure of the glottis and the explosive expulsion of air from the lungs by the work of abdominal and chest muscles.*
Promote systemic fluid hydration, as appropriate.	*Adequate fluid intake enhances liquefaction of pulmonary secretions and facilitates expectoration of mucus.*
Respiratory Monitoring [3350]	
Monitor rate, rhythm, depth, and effort of respirations.	*Provides a basis for evaluating adequacy of ventilation.*
Note chest movement, watching for symmetry, use of accessory muscles, and supraclavicular and intercostal muscle retractions.	*Presence of nasal flaring and use of accessory muscles during respirations may occur in response to ineffective ventilation.*
Auscultate breath sounds, noting areas of decreased or absent ventilation and presence of adventitious sounds.	*As fluid and mucus accumulate, abnormal breath sounds can be heard including crackles and diminished breath sounds resulting from fluid-filled air spaces and diminished lung volume.*
Auscultate lung sounds after treatments to note results.	*Assists in evaluating prescribed treatments and client outcomes.*
Monitor client's ability to cough effectively.	*Respiratory tract infections alter the amount and character of secretions. An ineffective cough compromises airway clearance and prevents mucus from being expelled.*
Monitor client's respiratory secretions.	*People with pneumonia commonly produce rust-colored, purulent sputum.*
Institute respiratory therapy treatments (e.g., nebulizer) as needed.	*A variety of respiratory therapy treatments may be used to open constricted airways and liquefy secretions.*
Monitor for increased restlessness, anxiety, and air hunger.	*These clinical manifestations would be early indicators of hypoxia.*
Note changes in SpO_2, tidal volume, and arterial blood gas values, as appropriate.	*Evaluates the status of oxygenation, ventilation, and acid–base balance.*

Evaluation

Outcome partially met. Ms. Singh coughs and deep breathes purposefully q1–2h during the day. Her fluid intake is approximately 1500 mL each day. Cough continues to be productive of moderately thick, rusty-colored sputum. Inspiratory crackles remain present in right lower lobe.

*The NOC # for desired outcomes and the NIC # for nursing interventions are listed in brackets following the appropriate outcome or intervention. Outcomes, interventions, and activities selected are only a sample of those by NOC and NIC and should be further individualized for each client.

APPLYING CRITICAL THINKING

1. What factors may have led the medical staff to suspect that Ms. Singh had more than a very bad cold? Would you have come to the same conclusion?
2. The care plan appropriately focuses on the acute care of this client. Once she is significantly improved, the nurse will perform discharge teaching. What areas should be included?
3. The client already has some signs of respiratory distress. What signs might indicate that her condition was deteriorating into a more emergency situation? How would you handle this?
4. It appears that the client's sputum has not been cultured. In caring for this client, what infection control guidelines would be needed?
5. The oxygen order is for a face mask at 6 L/min. She repeatedly pulls it off and you find it lying in the sheets. How might you intervene?

Answers to Applying Critical Thinking questions are available on the faculty resources site. Please consult with your instructor.

CONCEPT MAP

Altered Respiratory Status

Chapter 49 Review

CHAPTER HIGHLIGHTS

- Respiration is the process of gas exchange between the individual and the environment.
- The respiratory system contributes to effective respiration through pulmonary ventilation (the movement of air between the atmosphere and the lungs), the diffusion of oxygen and carbon dioxide across the pulmonary membrane, transport of oxygen from the tissues to the lungs and carbon dioxide from the tissues to the lungs, and transport of oxygen and carbon dioxide between the systemic capillaries and the tissues.
- Alveoli and the capillaries that surround them form the respiratory membrane, where gas exchange between the lungs and the blood occurs.
- Effective pulmonary ventilation, or breathing, requires clear airways, an intact central nervous system and respiratory center, an intact thoracic cavity and musculature, and adequate pulmonary compliance (stretch) and recoil.
- Gas exchange occurs by diffusion, as gas molecules move from an area of higher concentration to an area of lower concentration. At the respiratory membrane, oxygen moves from the alveolus into the blood, while carbon dioxide moves from the blood into the alveolus.
- Most oxygen (97%) is carried to the tissues loosely combined with hemoglobin in RBCs. Anemia, which is too few RBCs or low hemoglobin levels, impairs oxygen transportation.
- Respiratory regulation includes both neural and chemical controls to maintain the correct concentrations of oxygen, carbon dioxide, and hydrogen ions in body fluids. The body's respiratory center is located in the medulla oblongata and pons of the brain.
- Respiratory rates normally are highest in neonates and infants, gradually slowing to adult ranges.
- Aging affects the respiratory system: The chest wall becomes more rigid and lungs less elastic.
- Other factors affecting oxygenation include the environment, lifestyle, health status, medications, and stress.
- Respiratory function can be altered by conditions that affect the patency of the airway, movement of air into or out of the lungs, diffusion of oxygen and carbon dioxide between the alveoli and the pulmonary capillaries, and the transport of oxygen and carbon dioxide via the blood to and from the tissue cells.
- Hypoxia, insufficient oxygen in the tissues, can result from impaired ventilation (hypoventilation) or impaired diffusion, or from impaired oxygen transportation to the tissues because of anemia or decreased cardiac output.
- Airway obstruction interferes with ventilation. A low-pitched snoring sound, stridor, and abnormal breath sounds may accompany partial airway obstruction. Extreme inspiratory effort with no chest movement indicates complete upper airway obstruction.
- Normal respirations are quiet and unlabored; altered respiratory patterns include tachypnea, bradypnea, hyperventilation, hypoventilation, and dyspnea. Shortness of breath is a subjective sensation of not getting enough air.
- The nursing history includes questions about current or past respiratory problems and about lifestyle, presence of symptoms such as cough or shortness of breath, smoking and other risk factors, and medications.
- Diagnostic tests that may be performed to assess oxygenation include sputum and throat culture specimens; blood tests such as arterial blood gases; pulmonary function tests; and visualization procedures such as x-rays, lung scans, laryngoscopy, and bronchoscopy.
- Nursing diagnoses for the client with problems of oxygenation include altered respiratory status, altered breathing pattern, altered gas exchange, and inadequate physical energy for activities. These problems also may be the etiology for several other nursing diagnoses, including fatigue, insomnia, *and* social isolation.
- In discharge and home care planning, the nurse assesses the client's self-care abilities and need for assistive devices, home environment, compliance with medical regimen, and knowledge level. The ability of the family or support people to provide assistance and financial support and to cope with the changes is also assessed, as are community factors such as the environment and resources.
- The nurse teaches the client about home care activities to maintain a patent airway and gas exchange and to promote healthy breathing. Dietary modifications, prescribed medications, and specific procedures also are taught, and the nurse makes referrals to community agencies as needed.
- Nursing interventions to promote oxygenation include promoting healthy breathing, deep breathing and coughing, and hydration; administering medications; implementing measures to clear secretions (e.g., percussion, vibration, postural drainage, and mucus clearing devices); initiating and monitoring oxygen therapy; initiating or assisting with procedures to maintain the airway (e.g., artificial airways and suctioning); providing tracheostomy care; and monitoring chest drainage systems.
- The effectiveness of nursing interventions is evaluated by using the goals and desired outcomes identified in the planning stage of the nursing process. If a goal is not met, the nurse asks pertinent questions to assess the reason for not meeting the goal.

TEST YOUR KNOWLEDGE

1. A client with chronic pulmonary disease has a bluish tinge around the lips. The nurse charts which term to most accurately describe the client's condition?
   1. Hypoxia
   2. Hypoxemia
   3. Dyspnea
   4. Cyanosis
2. To prevent postoperative complications, the nurse assists the client with coughing and deep-breathing exercises. This is best accomplished by implementing which of the following?
   1. Coughing exercises 1 hour before meals and deep breathing 1 hour after meals
   2. Forceful coughing as many times as tolerated
   3. Huff coughing every 2 hours or as needed
   4. Diaphragmatic and pursed-lip breathing 5 to 10 times, 4 times a day
3. The nurse is preparing to perform tracheostomy care. Prior to beginning the procedure the nurse performs which action?
   1. Tells the client to raise two fingers to indicate pain or distress.
   2. Changes the twill tape holding the tracheostomy in place.
   3. Cleans the incision site.
   4. Checks the tightness of the ties and knot.
4. Which action by the nurse represents proper nasopharyngeal and nasotracheal suction technique?
   1. Lubricate the suction catheter with petroleum jelly before and between insertions.
   2. Apply suction intermittently while inserting the suction catheter.
   3. Rotate the catheter while applying suction.
   4. Hyperoxygenate with 100% oxygen for 30 minutes before and after suctioning.
5. Which of the following client conditions can alter respiratory function? Select all that apply.
   1. A client who has increasing thick secretions.
   2. A client with eupnea.
   3. A client with GI bleeding resulting in a large blood loss.
   4. A client with heart failure.
   5. A client with a temperature of 103.6°F (39.7°C) and experiencing severe pain.
6. While a client with chest tubes is ambulating, the connection between the tube and the water seal dislodges. Which action by the nurse is most appropriate?
   1. Assist the client to ambulate back to bed.
   2. Reconnect the tube to the water seal.
   3. Assess the client's lung sounds with a stethoscope.
   4. Have the client cough forcibly several times.
7. The nurse makes the assessment that which client has the greatest risk for a problem with the transport of oxygen from the lungs to the tissues? A client who has
   1. Anemia.
   2. An infection.
   3. A fractured rib.
   4. A tumor of the medulla.
8. Which term does the nurse document to best describe a client experiencing shortness of breath when lying down who must assume an upright or sitting position to breathe more comfortably and effectively?
   1. Dyspnea
   2. Hyperpnea
   3. Orthopnea
   4. Acapnea
9. A client with emphysema is prescribed corticosteroid therapy on a short-term basis for acute bronchitis. The client asks the nurse how the steroids will help him. The nurse responds by saying that the corticosteroids will do which of the following?
   1. Promote bronchodilation.
   2. Help the client to cough.
   3. Prevent respiratory infection.
   4. Decrease inflammation in the airways.
10. The nurse is planning to perform percussion and postural drainage. Which is an important aspect of planning the client's care?
    1. Percussion and postural drainage should be done before lunch.
    2. The order should be coughing, percussion, positioning, and then suctioning.
    3. A good time to perform percussion and postural drainage is in the morning after breakfast when the client is well rested.
    4. Percussion and postural drainage should always be preceded by 3 minutes of 100% oxygen.

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Outline the structure and physiology of the cardiovascular system.
2. Identify major risk factors for the development of cardiovascular disease and related health promotion objectives from *Healthy People 2020.*
3. Describe three major alterations in cardiovascular function.
4. Outline the nursing management of a client with cardiovascular disease.
5. Describe the critical nature of cardiopulmonary resuscitation.
6. Verbalize the steps used in
   a. Applying a sequential compression device.
7. Recognize when it is appropriate to assign aspects of applying a sequential compression device to assistive personnel.
8. Demonstrate appropriate documentation and reporting when applying a sequential compression device.

Introduction

The circulatory, or cardiovascular, system is responsible for the transport of oxygen, fluids, electrolytes, and products of metabolism via the blood to and from tissues.

Physiology of the Cardiovascular System

The respiratory and cardiovascular systems are closely linked and dependent on one another to deliver oxygen to the tissues of the body. Alterations in function of either system can affect the other and lead to tissue hypoxia (lack of oxygen).

The heart and the blood vessels make up the cardiovascular system. Together with blood, it is the major transport system of the body, bringing oxygen and nutrients to the cells and removing wastes for disposal. The heart serves as the system's pump, moving blood through the vessels to the tissues.

The Heart

The heart, a hollow, cone-shaped organ about the size of a fist, is located in the mediastinum, which is between the lungs and beneath the sternum. It is enclosed by a double layer of fibroserous membrane known as the **pericardium**. The parietal, or outermost, pericardium serves to protect the heart and anchor it to surrounding structures. The visceral pericardium adheres to the surface of the heart, forming the heart's outermost layer, the **epicardium**. The heart wall contains two additional layers: the **myocardium**, cardiac muscle cells that form the bulk of the heart and contract with each beat, and the **endocardium**, which lines the inside of the heart's chambers and great vessels.

Four hollow chambers within the heart, two upper **atria** and two lower **ventricles**, are separated longitudinally by the interventricular **septum**, forming two parallel pumps. The atria and ventricles are separated from one another by the **atrioventricular (AV) valves**: the tricuspid valve on the right and the bicuspid or mitral valve on the left. The valves are named for the number of cusps (or leaflets) present on the valve. The ventricles, in turn, are separated from the great vessels (the pulmonary arteries and aorta) by the **semilunar valves** (named for their crescent moon shape): the pulmonary (also called the pulmonic) valve on the right and the aortic valve on the left. The valves serve to direct the flow of blood, allowing it to move from the atria to the ventricles, and the ventricles to the great vessels, but preventing backflow.

Deoxygenated blood from the veins enters the right side of the heart through the superior and inferior venae

cavae (singular is vena cava). From there, it flows into the right ventricle, which pumps it through the pulmonary artery into the lungs for gas exchange across the alveolar–capillary membrane. Freshly oxygenated blood returns to the left atrium via the pulmonary veins. From here, the blood enters the left ventricle to be pumped out for systemic circulation through the aorta (Figure 50.1 ■).

Coronary Circulation

The heart muscle does not receive oxygen or nourishment from the blood within its chambers. Instead, it is supplied by the **coronary arteries**. The coronary arteries originate at the base of the aorta, branching out to encircle and penetrate the myocardium. These arteries fill during ventricular relaxation, bringing oxygen-rich blood to the myocardium (Figure 50.2 ■). If these arteries become clogged with atherosclerotic plaques or are obstructed by a blood clot, the myocardium is deprived of oxygen, and the client may develop chest pain (angina) or experience a myocardial infarction (heart attack). The cardiac veins drain the deoxygenated blood from the myocardium into the coronary sinus, which empties into the right atrium.

Figure 50.1 ■ The heart and blood vessels. The left side of the heart pumps oxygenated blood into the arteries. Deoxygenated blood returns via the venous system into the right side of the heart.

Figure 50.2 ■ The coronary arteries supply the heart muscle with oxygenated blood.

Cardiac Cycle

With each heartbeat, the myocardium goes through a cycle of contraction (systole) and relaxation (diastole). **Systole** is when the heart ejects (propels) the blood into pulmonary and systemic circulation. **Diastole** is when the ventricles fill with blood. The diastolic phase of the cardiac cycle is twice as long as the systolic phase. This is important because diastole (or ventricular filling) is largely a passive process. The longer diastolic phase allows this filling to occur. At the end of the diastolic phase, the atria contract, adding additional volume to the ventricles. This volume is sometimes called *atrial kick.* The relationship between the phases of the cardiac cycle and normal heart sounds is described in Table 50.1.

Cardiac Conduction System

Cardiac muscle contraction is a mechanical event that occurs in response to electrical stimulation. Cardiac muscle is unique in that, unlike skeletal muscle, it can generate electrical impulses and contractions independently of the nervous system. This unique property of heart muscle is called **automaticity**. A network of specialized cells and pathways known as the cardiac conduction system normally controls the electrical activity and contractions of the heart.

The primary pacemaker of the heart is the **sinoatrial (SA or sinus) node**, located where the superior vena cava enters the right atrium. The SA node normally initiates

TABLE 50.1 Cardiac Cycle and Heart Sounds

Sound	Phase of Cardiac Cycle
S_1—first sound	Beginning of ventricular systole; the sound is caused by closure of the atrioventricular valves—the tricuspid and the mitral.
S_2—second sound	Beginning of ventricular diastole; the sound is caused by closure of the semilunar valves—the aortic and pulmonic.

electrical impulses that are conducted throughout the heart and result in ventricular contraction. In adults, it usually discharges impulses at a regular rate of 60 to 100 times per minute, the "normal" heart rate. The impulse then spreads throughout the atria via the interatrial pathways. These conduction pathways converge and narrow through the **atrioventricular (AV) node**, slightly delaying transmission of the impulse to the ventricles. This delay allows the atria to contract slightly before ventricular contraction occurs. From the AV node, the impulse then progresses down through the intraventricular septum to the ventricular conduction pathways: the **bundle of His**, the right and left bundle branches, and the **Purkinje fibers**. These fibers terminate in ventricular muscle, stimulating contraction (Figure 50.3 ■).

Cardiac Output

As the ventricles contract during systole, blood flows out of the ventricles through the aorta and pulmonary artery into systemic and pulmonary circulation. The heart muscle then relaxes (the diastolic phase), allowing the ventricles to refill and cardiac muscle to be perfused. This repeated contraction and relaxation of the heart is known as the cardiac cycle. The cycle is repeated 60 to 100 times a minute in an adult, stimulated by impulses generated by the SA node.

With each contraction, a certain amount of blood, known as the stroke volume, is ejected from the ventricles into circulation. In adults, the average stroke volume is about 70 mL per beat. **Cardiac output (CO)** is the amount of blood pumped by the ventricles in 1 minute. Cardiac output is calculated by multiplying the **stroke volume (SV)**, the amount of blood ejected with each contraction, times the heart rate (HR). Thus, SV × HR = CO. Normal cardiac output is 4 to 8 L/min. Cardiac output is an important indicator of how well the heart is functioning as a pump. If CO is poor, oxygen and nutrients do not reach cells as needed, impairing tissue perfusion. Cardiac output is affected by several factors, as discussed next.

HEART RATE

An increased heart rate increases CO, even if the stroke volume does not change. In contrast, CO decreases when the heart rate falls if stroke volume remains constant. There are physiologic limits to the increase in CO that occurs with increased heart rate. Very rapid heart rates, more than 150 beats per minute in an adult, may not allow adequate time for the ventricles to fill, causing CO to fall. Heart rate is influenced by many factors including the autonomic nervous system, blood pressure, hormones such as thyroid hormone, and some medications.

PRELOAD

Preload is the degree to which muscle fibers in the ventricle are stretched at the end of the relaxation period (diastole). Preload largely depends on the amount of blood returning to the heart from venous circulation; increased volume causes increased stretch, leading to more forceful contraction of cardiac muscle fibers. This physiologic relationship is referred to as the Frank-Starling law of the heart, which states that the length of ventricular muscle fibers (stretch) at the end of diastole directly affects the strength (force) of contraction. For example, exercise increases venous return and therefore increases preload; in response, the heart contracts more forcefully, causing stroke volume and CO to increase during exercise.

Figure 50.3 ■ The conduction system of the heart. The impulse is initiated by the SA node (1), then travels to the AV node (2), the bundle of His (3), bundle branches (4), and finally to the Purkinje fibers (5).

From *Medical Terminology for Health Care Professionals* (9th ed., p. 261), by J. Rice, 2018. Reproduced by permission of Pearson Education, Inc., Hoboken, NJ.

CONTRACTILITY

Contractility is the natural ability of cardiac muscle fibers to shorten or contract. Stroke volume decreases if contractility is poor, reducing cardiac output. Contractility is affected by the autonomic nervous system and certain drugs. Drugs that affect contractility are called inotropic drugs; positive inotropic drugs increase contractility, and negative inotropic drugs decrease contractility.

AFTERLOAD

Afterload is the resistance that the ventricle must overcome during systole to eject blood into circulation. The right ventricle ejects blood into the pulmonary circulation, and the left ventricle ejects blood through the aortic valve to the systemic circulation. Blood flows from an area of higher pressure to an area of lower pressure. To move blood into the circulatory system, the ventricles must generate sufficient pressure to overcome vascular resistance or the pressure within the arteries, known as *afterload*. The right ventricle pumps blood into the low-pressure, low-resistance pulmonary vascular system; therefore, the pressures generated by the right ventricle are fairly low. The left ventricle, by contrast, pumps blood into the higher pressure systemic arterial system, generating much higher pressures and requiring more work. The higher the afterload, the harder the heart has to work to eject its contents, resulting in increased myocardial oxygen demand. For example, systemic vasoconstriction increases the arterial blood pressure and afterload, increasing the cardiac workload; vasodilation, on the other hand, reduces arterial pressure and the workload of the heart. Table 50.2 summarizes the factors related to cardiac function.

TABLE 50.2 Factors Related to Cardiac Function

Indicator	Definition
Cardiac output (CO)	Amount of blood ejected from the heart each minute; CO = SV × HR
Stroke volume (SV)	Amount of blood ejected from the heart with each beat
Heart rate (HR)	Number of beats each minute
Contractility	Inotropic state of the myocardium, strength of contraction
Preload	Left ventricular end diastolic volume, stretch of the myocardium
Afterload	Resistance against which the heart must pump

Blood Vessels

With each cardiac contraction, blood is ejected into a closed system of blood vessels that transport blood to the tissues and return it to the heart. The heart supports two circulatory systems: the low-pressure pulmonary system and the higher pressure systemic system.

Deoxygenated blood from the right ventricle enters the pulmonary system through the pulmonary arteries, which eventually branch out to form arterioles and the dense capillary networks that encompass the alveoli. Oxygen diffuses into the blood from the alveoli, and carbon dioxide diffuses into the alveoli from the blood. This diffusion occurs across the alveolar–capillary membrane. The blood then returns to the left side of the heart via venules and the pulmonary veins. Note that the pulmonary vascular system is the only part of the circulatory system in which arteries (which transport blood away from the heart) carry deoxygenated blood, and veins (which transport blood toward the heart) contain oxygenated blood.

The muscular left ventricle of the heart pumps oxygenated blood into the aorta. The blood then moves into major arteries that branch from the aorta and into successively smaller arteries, arterioles, and finally into the thin-walled capillary beds of organs and tissues. It is in the capillary beds that oxygen and nutrients are exchanged for metabolic waste products. The deoxygenated blood then returns to the heart through a series of venules and veins that become progressively larger until they empty into the superior and inferior venae cavae.

With the exception of capillaries, blood vessel walls have three distinct layers, or tunics. The innermost layer, the tunica intima, is smooth endothelium that facilitates blood flow. The tunica media is made up of elastic fibers and smooth muscle cells innervated by the autonomic nervous system. This allows vessels to constrict or dilate, depending on the needs of the body. The tunica media of arteries is thicker and more muscular than that of veins, a feature that helps maintain blood pressure and continuous circulation to the tissues. The outermost layer of blood vessels is the tunica adventitia, a layer of connective tissue that supports, protects, and anchors the vessel to surrounding tissues. Capillaries contain only one thin layer of tunica intima, allowing gases and molecules to diffuse between the blood and the tissues.

Arterial Circulation

Arterial circulation moves blood from the heart to the tissues, maintaining a constant flow to the capillary beds despite the intermittent pumping action of the heart.

Blood flow, the volume of blood flowing through a given vessel, organ, or the entire circulatory system over a specific period, is determined by pressure differences and resistance. Blood always moves from an area of higher pressure to an area of lower pressure. The greater the difference between pressures, the greater the blood flow. **Blood pressure (BP)** is the force exerted on arterial walls by the blood flowing within the vessel. See Chapter 28 ∞ for a further explanation of blood pressure. Mean arterial pressure (MAP) maintains blood flow to the tissues throughout the cardiac cycle. It is a product of cardiac output times **peripheral vascular resistance (PVR)**, or CO × PVR = MAP.

ANATOMY & PHYSIOLOGY REVIEW

Preload and Afterload

SUSAN M. TURLEY MA, BSN, RN, ART, CMT, MEDICAL TERMINOLOGY, 4th Ed., © 2017. Reprinted and Electronically reproduced by permission of Pearson Education, Inc., New York, NY.

QUESTIONS

Preload is affected by the amount of blood returning to the heart from the venous circulation. Review the figure.

1. Which side of the heart is primarily affected by preload?
2. What could cause an *increase* of venous blood return to the heart?
3. When would an increase in preload have a positive effect or outcome for the client?
4. When does an increase in preload have a negative effect or outcome for the client?
5. What medication classification decreases preload? (*Hint:* Think about what could cause a decrease in venous return of volume to the heart.)

Afterload is the resistance against which the heart must pump. Review the figure.

6. Which side of the heart is primarily affected by afterload?
7. What can cause an increase in afterload (e.g., what can cause the left side of the heart to work harder)?
8. Based on the physiology, afterload can be decreased by medications that would have what physiologic result or outcome?

Answers to Anatomy & Physiology Review questions are available on the faculty resources site. Please consult with your instructor.

Resistance is the opposite of flow; peripheral vascular resistance opposes blood flow to the tissues. PVR is determined by:

- The viscosity, or thickness, of the blood
- Blood vessel length
- Blood vessel diameter.

Venous Return

In contrast to the high-pressure arterial system, venous pressure is too low to adequately return blood from peripheral tissues to the heart without assistance. The fall in intrathoracic pressure that occurs with breathing draws blood upward toward the heart, an adaptation known as the respiratory pump. Skeletal muscle activity contributes to the muscular pump, as muscle contractions move blood toward the heart. Venous valves are vital in making these pumps work; once blood passes a valve, it cannot flow backward away from the heart. See Figure 50.1 earlier in this chapter for an illustration of the relationship between arteries and veins and the entire circulatory system.

Blood

Blood serves as the transport medium within the cardiovascular system, bringing oxygen and nutrients from the environment (via the lungs and gastrointestinal system) to the cells. Blood is a complex mixture of living elements (the blood cells) suspended in fluid (the plasma). Its primary functions are:

- Transporting oxygen, nutrients, and hormones to the cells, and metabolic wastes from the cells for elimination
- Regulating body temperature, pH, and fluid volume
- Preventing infection and blood loss.

As previously noted in Chapter 49 ∞, most oxygen is transported bound to hemoglobin. **Hemoglobin** is a major component of red blood cells (erythrocytes), the predominant cell present in blood. Because of hemoglobin's importance in oxygen transportation, anemia (too few red blood cells [RBCs] that contain too little or abnormal hemoglobin) interferes with oxygen delivery to the tissues, leading to fatigue and activity intolerance.

Lifespan Considerations

At birth, major changes occur in the cardiovascular system. As the lungs expand, pressure in the pulmonary vascular system falls, changing pressure relationships within the heart. The foramen ovale (an opening between the two atria of the fetal heart) closes as pressure on the right side of the heart falls and pressure on the left side increases. Arterial PO_2 rises and arterial PCO_2 falls, prompting closure of the ductus arteriosus (a short vessel between the pulmonary artery and aorta of the fetus).

Pulse rates are highest and most variable in newborns. The resting heart rate for a neonate ranges from 100 to 170 beats/min immediately after birth and then the average heart rate is 120 beats/min (Ball, Bindler, Cowen, & Shaw, 2017, p. 125). The heart rate decreases to 80 to 130 in infants up to 2 years of age, and continues to decrease throughout early childhood until reaching the adult rate of 60 to 100 by about age 10 years. Irregular heart rates are common in infants and young children, often increasing and decreasing with each breath. This pattern of irregularity is known as sinus arrhythmia, a normal variation in heart rate.

Congenital heart disease occurs in approximately 1% of all live births (Ball et al., 2017, p. 518). Deaths, however, from congenital heart disease have significantly decreased due to diagnostic advances and new surgical techniques. Acquired heart diseases, though rare in childhood, include rheumatic fever, an inflammatory disorder that may occur following streptococcal infection (e.g., strep throat) and lead to heart valve damage. For most individuals, however, the heart continues to function effectively well into older adulthood unless the blood supply to the heart muscle is impaired by blood vessel disease. **Atherosclerosis**, the buildup of fatty plaque within the arteries, is the primary contributor to cardiovascular disease (CVD), which is the leading cause of death in North America.

Children are rarely affected by diseases of the blood vessels, although the increase in childhood obesity has increased the incidence in this age group. Hypertension or elevated BP may be associated with obesity, sedentary lifestyle, and stress in children and adolescents. During middle adulthood, the incidence of hypertension increases significantly. Hypertension, known as the silent killer because of its lack of symptoms, is a major risk factor for sudden cardiac death in middle adulthood.

Factors Affecting Cardiovascular Function

Many factors affect cardiovascular function. Some of these factors are called risk factors, because, if present, they increase the risk of CVD. Risk factors have been identified for CVD, hypertension, and peripheral vascular disease, and the majority of these factors are the same for all three disorders.

Risk Factors

Major traditional risk factors for CVD in general are classified as either *nonmodifiable* (cannot be reduced) or *modifiable* (can be reduced). Newer, nontraditional

LIFESPAN CONSIDERATIONS Circulation

CHILDREN

- Blood pressure should be taken routinely on children after age 3 years, but is not typically evaluated before that age.
- Heart murmurs, extra sounds detected when listening to the heart, are common in children, especially in the preschool years. The vast majority are not associated with a pathology, but are due to normal blood flow or transitional physiologic processes that increase cardiac output (e.g., anemia, fever, exercise).

OLDER ADULTS

Normal changes of aging may contribute to problems of circulation in older adults, even when there is no actual pathology:

- Blood vessels become less elastic and have an increase in calcification. This results in restricted blood flow and a decrease of oxygen and nutrients delivered to tissues (heart, peripheral, and cerebral).
- Impaired valve function in the heart is often the result of increased stiffness and calcification and results in a decrease in cardiac output.
- A decrease of muscle tone in the heart results in a decrease in cardiac output.
- There is a decrease in baroreceptor response to blood pressure changes, making the heart and blood vessels less responsive to exercise and stress. This often results in dizziness, falls, orthostatic hypotension, and mental changes.
- A decrease in conduction ability in the heart also makes the heart less responsive to changes and stresses. This can also result in dizziness, falls, orthostatic hypotension, and mental changes.

All of these factors become important if the individual is challenged by stressors, such as exercise, stress, fever, surgery, or other changes. If challenged, the circulatory system of older adults is not as effective or as quick to return to normal. Individuals living with normal changes of aging and pathologic conditions of the circulatory system need to learn to balance diet, medications, and exercise. Nurses have a major role in working with these clients to develop appropriate interventions and provide teaching to help them maintain optimal functioning. Teaching clients to recognize any changes or worsening of their condition is very important. They need to know when to contact their primary care provider to make any needed changes. Changing lifestyles and fine-tuning medications can be critical, and nurses can be a part of this in every phase of the nursing process.

cardiovascular risk factors have also been identified (Box 50.1). It is important to remember that most CVD is preventable. Research has shown that individuals with low cardiovascular risk factors have a substantially reduced risk of developing CVD. Unfortunately, the processes that lead to CVD begin early in life. Research has shown that the major lifestyle behaviors associated with CVD (e.g., patterns of diet, physical activity, and tobacco use) do influence the development of CVD risk factors in childhood, adolescence, and adulthood.

BOX 50.1 Risk Factors for Cardiovascular Disease

HIGH RISK FACTORS

- Nonmodifiable
  - Heredity
  - Age
  - Gender
- Modifiable
  - Elevated serum lipid level
  - Hypertension
  - Cigarette smoking
  - Diabetes
  - Obesity
  - Sedentary lifestyle

OTHER RISK FACTORS

- Stress
- Alcohol
- Diet and nutrition

NONTRADITIONAL RISK FACTORS

- Metabolic syndrome (Met-S)
- C-reactive protein (CRP)
- Elevated homocysteine level

Nonmodifiable Risk Factors

The first nonmodifiable risk factor is *heredity.* There is a genetic influence on the development of CVD. That is, if a client has a parent with heart disease, he or she is at higher risk. In addition, members of certain racial and ethnic groups, such as African Americans, have a higher risk of developing CVD (Ferdinand, 2016). The second is *age.* Cardiovascular disorders primarily affect individuals over age 65. The third nonmodifiable risk factor is *gender.* Until menopause, estrogen has a protective effect in women, slowing the progression of atherosclerosis and reducing the risk of CVD. This effect is lost at menopause, when women's death rate from heart disease increases; however, it's not as great as men's (American Heart Association [AHA], 2016). Nurses need to assess and teach both men and women about cardiovascular risk factors.

Modifiable Risk Factors

Modifiable risk factors include elevated serum lipid levels, hypertension, cigarette smoking, diabetes, obesity, and sedentary lifestyle. Many of the *Healthy People 2020* objectives relate to these modifiable risk factors.

ELEVATED SERUM LIPID LEVELS

A strong link exists between elevated serum lipid levels and the development of CVD. Lipid disorders, also called dyslipidemias, are abnormalities of lipoprotein metabolism and include elevations of total cholesterol, low-density lipoprotein (LDL) cholesterol, or triglycerides, or deficiencies of high-density lipoprotein (HDL) cholesterol. A high dietary intake of saturated fats *increases* the total LDL levels, and intake of polyunsaturated fatty acids *decreases* total LDL in most individuals. Studies have also shown that *trans*-fatty acids (e.g., stick margarine, deep-fried foods) raise LDL levels and lower HDL levels, resulting in an increase in total cholesterol.

Older adults, just like all other age groups, have become more obese, which leads to high cholesterol levels. It is this kind of data that accounts for *Healthy People 2020* (Office of Disease Prevention and Health Promotion [DPHP], 2019b) promoting the following objectives: Increase the proportion of adults who have had their blood cholesterol checked within the preceding 5 years; reduce the proportion of adults with high total blood cholesterol levels; reduce the mean total blood cholesterol levels among adults; and increase the proportion of adults with elevated LDL cholesterol who have been advised by a healthcare provider regarding cholesterol-lowering management, including lifestyle changes and, if indicated, medication.

HYPERTENSION

Hypertension increases the risk of CVD in several ways. First, it increases the workload of the heart, increasing oxygen demand and coronary blood flow. The increased workload also causes hypertrophy of the ventricles. Over time this can contribute to heart failure. Second, hypertension causes endothelial damage to the blood vessels, which stimulates the development of atherosclerosis. Atherosclerotic plaques cause a worsening of hypertension by narrowing the vessel lumens and decreasing vessel elasticity. Therefore, there is a cyclical relationship between these two conditions that raises an affected individual's risk for CVD.

High sodium intake can affect blood pressure and contribute to the development of hypertension. First, it may increase the release of natriuretic hormone, which indirectly contributes to hypertension. Additionally, sodium stimulates vasopressor mechanisms, which cause vasoconstriction. There is also evidence that other factors such as low potassium, calcium, and magnesium intake may contribute to vasoconstriction and the development of hypertension.

Healthy People 2020 (DPHP, 2019b) includes the following objectives relating to hypertension: Reduce the proportion of adults, children, and adolescents with hypertension; increase the proportion of adults with prehypertension and hypertension who meet the recommended guidelines for body mass index (BMI), saturated fat consumption, sodium intake, physical activity, and moderate alcohol consumption; increase the proportion of adults with hypertension who are taking the prescribed

medications to lower their blood pressure; and increase the proportion of adults with hypertension whose blood pressure is under control.

CIGARETTE SMOKING

The cardiovascular system is affected by cigarette smoking. Nicotine increases heart rate, blood pressure, and peripheral vascular resistance, increasing the heart's workload. Smoking causes vasoconstriction, and in areas where vessels already are narrowed by atherosclerosis, tissue oxygenation can be impaired.

Healthy People 2020 (DPHP, 2019e) includes many objectives relating to tobacco use, including, but not limited to: Reduce cigarette smoking by adolescents and adults; increase smoking cessation attempts by adolescent and adult smokers and during pregnancy; increase tobacco cessation counseling in healthcare settings; and establish laws that prohibit smoking in public places and worksites.

DIABETES

Diabetes mellitus increases the risk of CVD and myocardial infarction (MI). High blood glucose levels are associated with accelerated development of atherosclerosis as well as high levels of serum lipids and triglycerides. Closely monitoring blood glucose levels in clients with diabetes and checking blood glucose levels in all clients for the development of increased levels are important nursing functions. Control of blood glucose levels can greatly reduce risk and slow development of atherosclerosis. Examples of objectives in *Healthy People 2020* (DPHP, 2019a) that pertain to diabetes include the following: Reduce the annual number of new cases of diagnosed diabetes in the population; reduce the death rate among individuals with diabetes; reduce the rate of lower extremity amputations in individuals with diagnosed diabetes; improve glycemic control among individuals with diabetes; and increase the proportion of individuals with diagnosed diabetes who receive formal diabetes education.

OBESITY

Obesity and diabetes are major health problems that are rapidly getting worse in the United States. In addition, individuals with obesity have an increased risk for the development of CVD because obesity is often accompanied by elevated serum lipid levels and is associated with hypertension. Thus, adults who are obese are at risk for diabetes and hypertension. Additionally, obesity places an increased workload on the heart, which increases oxygen demand. Research has shown that obese individuals have an increased risk for heart failure and death, and that risk increases in proportion to the degree of obesity.

Examples of objectives in *Healthy People 2020* (DPHP, 2019c) that pertain to weight include: Increase the proportion of adults who are at a healthy weight; reduce the proportion of children and adolescents who are considered obese; and increase the proportion of physician office visits that include counseling or education related to nutrition or weight.

SEDENTARY LIFESTYLE

Regular physical activity is associated with a reduction in the risk of death due to CVD, whereas a sedentary lifestyle is associated with increased risk. Physical exercise or activity increases the heart rate and, hence, the supply of oxygen in the body. With regular vigorous exercise, the heart muscle becomes more powerful and efficient. Aerobic exercise slows the atherosclerotic process, directly reducing the risk of CVD, and decreases the risks of obesity and diabetes mellitus, therefore indirectly reducing risk of CVD as well.

A healthy lifestyle that includes a heart-healthy diet and physical activity promotes cardiovascular health. This is true throughout the lifespan. Because children and adolescents spend a great deal of time in school, one of the *Healthy People 2020* (DPHP, 2019d) objectives is to increase the number of states with licensing regulations for physical activity in child care that require activity programs providing large muscle or gross motor activity, development, and/or equipment. The *Healthy People 2020* objectives also include increasing the proportion of adolescents and adults who meet current federal physical activity guidelines for aerobic physical activity and for muscle-strengthening activity.

Other Risk Factors

The American Heart Association (2016) includes other risk factors that contribute to heart disease risk: stress, alcohol, and diet and nutrition.

STRESS

How one responds to stress may be a contributing factor. For example, some individuals may react to stress by developing or increasing other major risk factors such as overeating, start smoking, or increase the amount of their smoking. It is important for nurses to share stress management tools.

ALCOHOL

Drinking too much alcohol can increase blood pressure, increase risk of cardiomyopathy, contribute to high triglycerides, produce irregular heartbeats, and contribute to obesity (AHA, 2016). There is a cardioprotective effect of *moderate* alcohol consumption. This effect, however, is based on a limit of one drink per day. One drink can equal any one of the following: 12 oz. of regular beer, 5 oz. of wine, 1.5 oz of 80-proof spirits, or 1 oz. of 100-proof spirits (Harvard Health Publishing, 2018).

DIET AND NUTRITION

The food and amount of food one eats can also affect the modifiable risk factors: cholesterol, blood pressure, diabetes, and obesity. A healthy diet (see Chapter 46 ∞) and lifestyle are the best weapons in the fight against cardiovascular disease.

Nontraditional Risk Factors

Other emerging modifiable risk factors that may influence cardiovascular function include the presence of metabolic syndrome or C-reactive protein or an elevated homocysteine level.

METABOLIC SYNDROME

Metabolic syndrome (Met-S) is a cluster of cardiovascular risk factors that increase the risk for cardiovascular disease, diabetes, and death. Five risk factors are included in Met-S: central obesity (e.g., increased waist circumference), increased triglycerides, decreased HDL cholesterol, hypertension, and elevated fasting glucose. An individual is considered to have metabolic syndrome when at least three of the five risk factors are present. Each risk factor is usually treated individually. Overall, lifestyle activities and behaviors, such as nutrition and physical activity, are the best preventions for the development of Met-S risk factors.

C-REACTIVE PROTEIN

Many studies have shown that acute myocardial infarction (AMI) involves an inflammatory process. A useful screening test for this inflammatory process is the **C-reactive protein (CRP)** assay. However, a CRP can be elevated in other inflammatory conditions (e.g., trauma, infections, rheumatoid arthritis). Currently a more highly sensitive measurement to detect CRP is used for cardiovascular risk assessment and is called hs-CRP. An hs-CRP level of 1 mg/L is considered low risk for CVD. Moderate risk is an hs-CRP between 1 and 3 mg/L, and greater than 3 mg/L is considered high risk for CVD (Stöppler, 2018). Usually, CRP screening is completed along with cholesterol screening to determine cardiovascular risk assessment. If the results are high, smoking cessation, diet, and exercise are recommended guidelines to reduce the CRP and cholesterol levels.

ELEVATED HOMOCYSTEINE LEVEL

Homocysteine is an amino acid that has been shown to be increased in many individuals with atherosclerosis. Clients with elevated homocysteine levels may have an increased risk of MI, CVD, stroke, and peripheral vascular disease. It is thought that individuals can reduce their homocysteine level by taking a multivitamin that provides folate, vitamin B_6, vitamin B_{12}, and riboflavin. However, clinical trials that attempted to lower homocysteine levels through B-vitamin treatment have varied in their results. As a result, there is controversy regarding the significance of homocysteine as a risk factor for CVD and stroke (Chrysant & Chrysant, 2018).

QSEN Patient-Centered Care: Gender Disparities in Clients with Cardiovascular Disease

Once considered a man's disease, more women than men are now living and dying with CVD (Banman & Sawatzky, 2017; [CDC], 2017). Women's risk factors are different from men's. For example, women with diabetes and those who smoke are at higher risk than men who have diabetes or smoke. Other risk factors for women include pregnancy complications such as preeclampsia, gestational diabetes, and pregnancy-induced hypertension (Kalman & Wells, 2018, p. 22). The Association of Women's Health, Obstetric and Neonatal Nurses (AWHONN, 2018) reports that risk factor trends for women are of concern. For example, more women than men have metabolic syndrome; 2 out of 3 women older than 20 are overweight or obese, which contributes to the development of diabetes; and more women over 65 years old have hypertension than men of similar age. Additionally, in the past 40 years, mortality rates from CVD have decreased for men but have not improved for women age 25 to 34 (AWHONN, 2018). Researchers are asking why this is, especially if estrogen is considered to be cardioprotective in younger women.

Many women are not aware that their MI symptoms may be different from men's. For example, men often describe chest pain as "an elephant sitting on my chest," whereas women may feel it as pressure or discomfort or have pain in the neck, jaw, throat, abdomen, or back (CDC, 2017). Other symptoms that women may experience (e.g., shortness of breath, indigestion, unusual fatigue, insomnia, anxiety) are vague and easily missed by healthcare providers (Kalman & Wells, 2018).

Prevention strategies have helped reduce mortality rates for men but the rates have not decreased as rapidly for women. One possible reason for this difference is that women may not be aware of their risk for heart disease and, therefore, have minimal concern for adopting more health promotion activities. Nurses are often a woman's first and most consistent point of contact with the healthcare system. Thus, it is important for nurses to assess for and discuss CVD risk factors with their female clients.

Alterations in Cardiovascular Function

Cardiovascular function can be altered by conditions that affect:

1. The function of the heart as a pump
2. Blood flow to organs and peripheral tissues
3. The composition of the blood and its ability to transport oxygen and carbon dioxide.

Three major alterations in cardiovascular function are decreased cardiac output, impaired tissue perfusion, and disorders that affect the composition or amount of blood available for transport of gases.

Decreased Cardiac Output

Although the heart is normally able to increase its rate and force of contraction to increase cardiac output during exercise, fever, or other times of need, some conditions interfere with these mechanisms.

The vessels that supply blood to the heart muscle may become occluded by atherosclerosis or a blood clot, shutting off the blood supply to a portion of the myocardium. When this happens, the tissue becomes necrotic and dies, a condition known as a **myocardial infarction (MI)** or *heart attack.* If a large portion of the heart muscle is affected, particularly in the left ventricle, cardiac output falls because the affected muscle no longer contracts. Signs and symptoms of MI are variable and may include the following:

- Chest pain; substernal or radiating to the left arm, jaw
- Nausea
- Shortness of breath
- Diaphoresis.

Heart failure may develop if the heart is unable to keep up with the body's need for oxygen and nutrients to the tissues. Heart failure usually occurs because of MI, but it may also result from chronic overwork of the heart, such as in clients with uncontrolled hypertension or extensive arteriosclerosis. In left-sided heart failure, the vessels of the pulmonary system become congested or engorged with blood. This may cause fluid to escape into the alveoli and interfere with gas exchange, a condition known as *pulmonary edema.* Signs of heart failure may include the following:

- Pulmonary congestion; adventitious lung sounds
- Shortness of breath
- Dyspnea on exertion (DOE)
- Increased heart rate
- S_3 heart sound
- Increased respiratory rate
- Nocturia
- Orthopnea
- Distended neck veins.

Other diseases such as myocarditis and cardiomyopathy also can affect the heart muscle, impairing its ability to contract and pump. Box 50.2 gives examples of conditions that may precipitate heart failure.

BOX 50.2 Examples of Conditions That May Precipitate Heart Failure

CONDITIONS THAT INCREASE PRELOAD
- Hypervolemia
- Valvular disorders such as mitral regurgitation
- Congenital defects such as patent ductus arteriosus

CONDITIONS THAT INCREASE AFTERLOAD
- Hypertension
- Atherosclerosis

CONDITIONS THAT AFFECT MYOCARDIAL FUNCTION
- Myocardial infarction
- Cardiomyopathy
- Coronary artery disease

Very irregular or excessively rapid or slow heart rates can also decrease cardiac output. With irregular or very rapid heart rates, the ventricles may not fill adequately between beats, so stroke volume (amount pumped with each beat) falls. If the heart rate is too slow, the heart may not be able to increase its stroke volume enough to maintain the cardiac output. Abnormalities of heart rate and rhythm are known as dysrhythmias and can be identified on an electrocardiogram (ECG).

Alterations in the structure of the heart can affect cardiac output. Congenital heart defects result in abnormal blood flow and may even allow venous and arterial blood to mix. Oxygen supply to body tissues is affected in this case. Acquired heart diseases such as bacterial endocarditis and rheumatic fever may damage the heart valves, affecting the flow of blood within the heart and to the great vessels. For example, if the mitral (bicuspid) valve becomes scarred and stenotic (constricted), it may not open fully, impairing filling of the left ventricle. Or, if the mitral valve does not fully close (mitral insufficiency), blood may escape back or regurgitate into the left atrium instead of entering the aorta each time the ventricle contracts.

Impaired Tissue Perfusion

Atherosclerosis is by far the most common cause of impaired blood flow to organs and tissues. As vessels narrow and become obstructed, distal tissues receive less blood, oxygen, and nutrients. **Ischemia** is a lack of blood supply due to obstructed circulation. Any artery in the body may be affected by atherosclerosis, although the effects are most often associated with coronary arteries, vessels supplying blood to the brain, and arteries in peripheral tissues. Partial obstruction of coronary arteries causes myocardial ischemia, often resulting in angina pectoris; if the obstruction is complete a heart attack (MI) occurs. Partial obstruction of cerebral vessels may cause a transient ischemic attack (TIA); if the obstruction is complete, a stroke occurs. Peripheral vascular disease leads to ischemia of distal tissues such as the legs and feet. Gangrene and amputation may result. Signs of impaired peripheral arterial circulation in the legs and feet may include the following:

- Decreased peripheral pulses
- Pain or paresthesias
- Pale skin color
- Cool extremities
- Decreased hair distribution.

The risk factors for peripheral atherosclerosis are similar to those for CVD and include cigarette smoking, high fat intake, obesity, and a sedentary lifestyle. Hypertension and diabetes also increase the risk for atherosclerosis, particularly if the blood pressure or blood glucose levels are not maintained at near-normal levels.

Although much less common, other disorders such as vessel inflammation, arterial spasm, and blood clots also can occlude blood vessels, leading to ischemia. Tissue edema can impair flow through vessels and can increase the distance oxygen and nutrients must diffuse across to reach cells.

On the venous side, incompetent valves may allow blood to pool in veins, causing edema and decreasing venous return to the heart (Figure 50.4 ■). Veins also can become inflamed, reducing blood flow and increasing the risk of thrombus (clot) formation. Thrombi may then break loose, becoming emboli. These emboli tend to travel as far as the pulmonary circulation where they become trapped in small vessels (pulmonary emboli), occluding blood supply to the capillary side of the alveolar–capillary membrane. Although alveolar ventilation to the affected area often remains adequate, no gas exchange occurs there because of impaired blood flow. Signs of acute pulmonary embolism (PE) can be nonspecific and variable but may include the following:

- Sudden onset of shortness of breath
- Pleuritic chest pain.

Figure 50.4 ■ *Left:* Vein with competent valve; *right*, vein with incompetent valve that allows blood to pool in the veins.
From *Medical Terminology for Health Care Professionals* (9th ed., p. 293), by J. Rice, 2018. Reproduced by permission of Pearson Education, Inc., Hoboken, NJ.

Blood Alterations

Because most oxygen is transported to the tissues in combination with hemoglobin, the problems of inadequate RBCs, low hemoglobin levels, or abnormal hemoglobin structure can affect tissue oxygenation. Anemia has several different causes: RBCs are lost along with other components because of acute or chronic bleeding; if diet is deficient in iron or folic acid, hemoglobin and RBCs are not formed adequately; and some disorders cause RBCs to break down excessively. Clients with sickle cell disease produce an abnormal form of hemoglobin and may experience tissue ischemia during exacerbations of the disease. Signs of anemia may include the following:

- Chronic fatigue
- Pallor
- Shortness of breath
- Hypotension.

Blood volume also affects tissue oxygenation. If the blood volume is inadequate, as in hemorrhage or severe dehydration, blood pressure and cardiac output fall, and tissues may become ischemic. Conversely, clients with hypervolemia (excess blood volume), which can result from fluid retention or kidney failure, may develop heart failure and peripheral edema, also leading to tissue ischemia.

●○● NURSING MANAGEMENT

Assessing

Nursing assessment of the cardiovascular system status includes a history, physical examination, and a review of relevant diagnostic data, including cardiac monitoring.

Nursing History

A comprehensive nursing history should include data regarding:

- Current and past cardiovascular problems
- Family history of cardiovascular problems such as high blood pressure, increased cholesterol level, heart attack, and stroke
- Other medical history including diabetes and respiratory disorders
- Exercise and activity level
- History of tobacco use
- Diet, including fat and salt intake, alcohol intake, caffeine intake including soft drinks and chocolate

ASSESSMENT INTERVIEW Circulation

CURRENT OR PAST CARDIOVASCULAR PROBLEMS

- Do you have high blood pressure?
- Do you have any history of heart disease such as angina, heart attack, or heart failure? Have you ever had a cardiac catheterization, angiogram, or angioplasty? Have you ever been diagnosed with rheumatic fever, endocarditis, pericarditis, or other diseases of the heart? If so, when? Have you had cardiac surgery or stent placement?
- Have you ever been told that you have peripheral vascular disease? Do you ever develop pain in the calves of your legs when walking? How far can you walk before it occurs? What do you do to relieve it? Have you had surgery on your blood vessels?
- Do your feet and ankles ever swell or feel very cold, numb, or tingling? Do you experience pain in your feet? Is the pain changed by position?
- Do you become extremely fatigued with activity? Have you ever been told that you are anemic?

MEDICATION HISTORY

- Have you taken or do you take any over-the-counter or prescription medications for your heart or blood pressure or to increase blood flow?
- Do you take any anticoagulants or other medications to "thin" your blood?

LIFESTYLE

- Do you use tobacco? If so, what kind?
- Do you exercise? What kind of exercise and how often?
- How often do you drink alcoholic beverages such as beer, wine, or liquor? How much do you usually drink at a time?

- Presence of any symptoms such as pain, shortness of breath, dizziness, fatigue, palpitations, cough, and fainting
- Medications for heart, blood pressure, circulation, and cholesterol
- Lifestyle, including social support, stressors, and methods of coping.

Physical Assessment

To examine the cardiovascular system, a nurse first evaluates blood pressure in both arms (the results should be within 10 mmHg of each other) and palpates peripheral pulses for their strength and equality. The apical pulse is auscultated for rate, rhythm, and the quality of heart sounds. Apical pulse rate and peripheral pulse rates should not vary more than a few beats per minute from one another. Carotid arteries are auscultated for bruits (a sound of turbulence), which may indicate atherosclerosis and narrowing (see Chapter 29 ∞). Also important as an indicator of cardiac function is lung sounds. By auscultating the lungs for adventitious sounds, the nurse assesses for increased pulmonary vessel pressure secondary to decreased cardiac output.

Much information about the cardiovascular system is obtained by assessing the skin for color, temperature, hair distribution, lesions, and edema. Clients with extensive peripheral vascular disease may have cool feet with weak pulses and shiny, nearly hairless shins and feet. Pitting edema of the feet and ankles may be noted in clients with heart failure. See Chapter 29 ∞ for specific techniques for assessing the respiratory and cardiovascular systems.

One noninvasive measure used to assess for peripheral vascular disease is the ankle brachial index (ABI). This is the ratio of arterial pressure in the ankle compared with that in the arm. The ABI is a simple, reliable means for diagnosing peripheral arterial disease (PAD) (Park, 2016). The ABI has been traditionally determined using a conventional sphygmomanometer and a Doppler instrument. Aneroid BP cuffs, however, are being replaced by automated blood pressure equipment. To perform an ABI, the client has to be supine for 5 to 10 minutes while the nurse gathers BP cuffs, a handheld Doppler instrument, and ultrasound gel. Place a BP cuff on the client's right arm and right ankle. After applying the gel, use the Doppler to determine the client's systolic pressure in the right arm and right ankle using the right dorsalis pedis and posterior tibial arteries. Repeat this procedure for the client's left arm and ankle. Use the higher ankle pressure (dorsalis pedis or posterior tibial) for each lower extremity and the higher arm pressure. Box 50.3 explains how to measure the ABI.

Diagnostic Studies

Many diagnostic studies are available that can help to identify the presence of CVD. Diagnostic studies may also be used as screening tools to identify increased risk so that modifications can be made to reduce the risk of development of CVD. An example of this is the serum lipid level. If a client has an elevated serum lipid level, he or she should be educated about the effects of diet and the importance of reducing lipids to reduce the risk of CVD.

BOX 50.3 Measurement of an Ankle Brachial Index (ABI)

The ABI measurement compares the systolic blood pressure of the lower extremity with the systolic blood pressure of the brachial artery. A ratio is calculated based on the results.

$$\text{ABI} = \frac{\text{systolic pressure of the ankle}}{\text{systolic pressure of the arm}}$$

Example

$$\text{ABI} = \frac{\text{132 systolic pressure of ankle}}{\text{124 systolic pressure of arm}} = 1.06$$

Interpretation of ABI:
- 1.00–1.40: normal
- 0.9–1.0: acceptable
- 0.8–0.90: some arterial disease
- 0.5 – 0.8: moderate arterial disease
- Less than 0.5: severe arterial disease

From *Measuring and Understanding the Ankle-Brachial Index (ABI)*, by Stanford Medicine, n.d.

Cardiac Monitoring

Cardiac monitoring allows for continuous observation of the client's cardiac rhythm. Cardiac monitoring is a recording of the heart's electrical activity. It is used in many instances: for clients who have known or suspected CVD, during and after surgery, to monitor responses to drug therapy, and to monitor clients at risk for serious complications such as shock. Electrodes placed on the client's chest are attached to a monitor cable and bedside monitor (Figure 50.5 ■). The monitor is equipped with alarms used to warn of potential problems such as very fast, very slow, or irregular heart rates. The alarm limits are usually set for 20 beats higher and lower than the client's baseline rate, often at 100 to 110 and 50 to 55, respectively, for adults. For ambulatory clients (in the hospital or at home), the electrodes connect to a transmitter unit (also called telemetry). This unit electronically sends the signal to a central monitor for display or may store the information to be retrieved later in the primary care provider's office. Another name for this type of ambulatory monitoring is a Holter monitor. Electrodes are attached and the client wears the monitor for 24 hours. A continuous ECG is recorded and later analyzed for irregularities.

Figure 50.5 ■ A client with cardiac monitoring.

Electrocardiography most commonly uses 12 "leads" or 12 different views of the heart. In contrast, cardiac monitoring uses 2 or 3 leads at any given time.

Clinical Alert!

It is important to remember that ECG monitoring is a recording of the electrical activity of the heart; it does not reflect mechanical contraction and cardiac output. *Always* remember to check the client to assess for cardiac function. Just looking at the ECG does not give an assessment of the client's status.

Blood Tests

Specimens of venous blood can be used for several tests that may reflect some aspect of cardiovascular functioning.

Because hemoglobin is the molecule to which oxygen attaches, an individual's hemoglobin level gives an indication of the oxygen-carrying capacity of the blood. A decreased hemoglobin level increases the risk of oxygen deficit in body tissues, especially when CVD is present.

Measurement of serum electrolytes is important for clients with cardiovascular problems because electrolyte abnormalities such as hyperkalemia (higher than normal potassium) and hypokalemia (lower than normal potassium) can have a critical effect on the heart. Serum levels of magnesium, calcium, sodium, and phosphorus are also important to assess.

Measurement of certain enzyme levels in the blood is an important part of the diagnostic evaluation of clients with chest pain. Enzymes such as **creatine kinase (CK)** and **troponin** are released into the blood during an MI, as a result of cell membrane damage. Elevated levels of these enzymes can help differentiate between an MI (when myocardial cells actually die) and chest pain from a different cause such as angina or pleuritic pain.

Hemodynamic Studies

Hemodynamics is the study of the forces or pressures involved in blood circulation. Hemodynamic studies or monitoring procedures may be performed to evaluate fluid status and cardiovascular function. Parameters evaluated in hemodynamic studies include heart rate, arterial blood pressure, central venous pressure, pressures in the pulmonary vascular system, and CO. Some of these parameters—for example, heart rate, arterial blood pressure, and venous pressure—are measured directly using an arterial, central venous, or pulmonary artery catheter; others, such as stroke volume and cardiac output, are calculated. Hemodynamic studies are performed in a diagnostic cardiac laboratory and require informed consent. Clients in intensive and cardiac care units may undergo continuous hemodynamic monitoring to evaluate cardiovascular status and the effect of interventions. Nurses in these units are responsible for obtaining accurate readings and maintaining the integrity of the system.

Diagnosing

Examples of diagnoses for clients with circulation problems can include inadequate cardiac output, impaired tissue perfusion, and blood alterations (e.g., decreased RBCs, low hemoglobin level, anemia).

Planning

When planning care the nurse identifies nursing interventions that will assist the client to achieve these broad goals:

- Maintain or restore an adequate cardiac output.
- Maintain or improve tissue perfusion.

Obviously, goals will vary according to the diagnosis and the signs and symptoms for each individual. Appropriate preventive and corrective nursing interventions that relate to these must be identified. Specific nursing activities can be selected to meet the client's individual needs. Examples of NIC interventions related to decreased cardiac output and tissue perfusion include the following:

- Circulatory Care: Arterial Insufficiency
- Cardiac Care
- Hemodynamic Regulation.

To promote the transport of oxygen and carbon dioxide, the nurse can optimize CO by reducing stress, planning appropriate activities, and positioning the client for improved vascular blood flow.

Implementing

Promoting Circulation

Most individuals in good health give little thought to their cardiovascular function. Changing position frequently, ambulating, and exercising usually maintain adequate cardiovascular functioning. See Client Teaching for other ways to promote a healthy heart.

Immobility is harmful to cardiovascular function. Without activity of the calf and leg muscles, blood pools in the veins of the lower extremities. This stagnant (sluggish) blood flow may allow clots to develop (venous thrombosis). With time, these clots can break loose and become emboli, eventually lodging in the small vessels of the pulmonary vascular system. Blood flow and gas exchange in the lungs are then impaired.

Many nursing interventions can help clients maintain cardiac and vascular function. They may be classified as vascular and cardiac.

CLIENT TEACHING **Promoting a Healthy Heart**

- Exercise regularly, participating in at least 30 minutes of moderate-intensity aerobic exercise 5 times a week.
- Do not smoke.
- Maintain your ideal weight.
- Use the DASH eating plan (Dietary Approaches to Stop Hypertension) by eating foods low in saturated fat, total fat, and cholesterol, and high in fruits, vegetables, and low-fat dairy foods.
- Drink alcohol in moderation, if at all, consuming no more than 1 cocktail or 1 glass of wine or beer daily.
- Reduce stress and manage anger.
- Effectively manage diabetes and hypertension, maintaining blood glucose and blood pressure levels within normal limits.
- If female, discuss with your healthcare provider the advantages and risks of hormone replacement therapy after menopause (or after a total hysterectomy).
- Consult your primary care provider about the advisability of low-dose aspirin therapy to further reduce the risk of CVD.

CLIENT TEACHING Home Care and Circulation

MAINTAINING CARDIAC OUTPUT AND TISSUE PERFUSION

- Teach the symptoms of heart failure to the client and family and emphasize when to contact the primary care provider.
- Teach the client about the importance of maintaining regular physical activity to promote circulation and vascular health. Emphasize the need to increase activity levels gradually with the goal of exercising (walking, swimming, weight training, or aerobic exercise as recommended by the care provider) for at least 30 minutes 5 times per week.
- Instruct the client to avoid exposure to cold, wearing warm clothing as needed.
- Teach cardiopulmonary resuscitation or refer for instruction.

DIETARY ALTERATIONS

- Instruct the client and family about prescribed dietary restrictions such as a low-sodium diet. Refer to a dietitian as needed for further instruction.
- Discuss dietary measures to reduce the risk of atherosclerosis, including reducing total and saturated fats in the diet, reducing weight if obese, and increasing the intake of dietary fiber.

MEDICATIONS

- Instruct the client and family about prescribed medications, including effects, side effects, and administration.

Vascular

- Position with the legs elevated to promote venous return to the heart. This is particularly important for clients with venous dysfunction. Care should be taken, however, to avoid this position in clients with cardiac dysfunction because it will increase preload and may increase stress on the heart.
- Avoid pillows under the knees or more than 15 degrees of knee flexion to improve blood flow to the lower extremities and reduce venous stagnation.
- Encourage leg exercises (such as flexion and extension of the feet, active contraction and relaxation of calf muscles) for a client on bedrest, and promote ambulation as soon as possible.
- Encourage or provide frequent position changes.

Cardiac

- Position the client in a high-Fowler's position to decrease preload and reduce pulmonary congestion.
- Monitor intake and output. Fluid restriction is usually not required for clients with mild to moderate cardiac dysfunction. With severe heart failure, a fluid restriction may be ordered.

Medications

Many classes of medications are administered to clients with cardiovascular disorders. Drugs such as nitrates, calcium channel blockers, and angiotensin-converting enzyme (ACE) inhibitors reduce the workload of the heart and prevent vasoconstriction. Various drugs are used to treat cardiac dysrhythmias. Positive inotropic drugs such as digoxin are used to increase the contractile strength of the heart. (See the Drug Capsule feature on digoxin in Chapter 28 ∞.) Beta-adrenergic blocking agents such as propranolol or metoprolol may be given to block the sympathetic nervous system action on the heart and decrease oxygen consumption. Direct vasodilators may be used for clients with peripheral vascular disease and sometimes hypertension. Often clients are on numerous medications, and it is an important role of the nurse to help the client understand the purposes, effects, and side effects of the different medications.

Administering medications is an important nursing function. Nurses are responsible for assessing for the effects of medications and also for potential complications. Examples include:

- When diuretics are administered, the nurse assesses intake, output, and serum potassium level (because many diuretics can lower potassium level).
- When positive inotropic medications are administered, the nurse should assess blood pressure, heart rate, peripheral pulses, and lung sounds as indicators of cardiac output.
- When antihypertensive medications are administered, it is critical for the nurse to monitor blood pressure. Additionally, many antihypertensive medications can cause orthostatic hypotension.

Preventing Venous Stasis

When clients have limited mobility or are confined to bed, venous return to the heart is impaired and the risk of venous stasis increases. Immobility is a problem not only for ill or debilitated clients but also for some travelers who sit with legs dependent for long periods in a motor vehicle or an airplane.

Venous stasis may allow clots (venous thrombosis) to develop in a deep vein, often in the thigh or calf. This is called deep venous thrombosis or deep vein thrombosis (DVT). If the thrombus breaks free, it can travel and become a PE where it blocks a pulmonary artery or one of its branches. Blood flow and gas exchange in the lungs are then impaired. If the clot is large enough, sudden death can occur. DVT in the popliteal vein and those above it are strongly associated with the development of PEs (Roberts & Lawrence, 2017, p. 39). The term *venous thromboembolism* (VTE) incorporates both DVT and PE. VTE is one of the most common preventable causes of hospital-related death, especially among older adults because advancing age is a major risk for VTE (Dunn & Ramos, 2017).

Preventing venous stasis is an important nursing intervention to reduce the risk of complications following surgery, trauma, or major medical problems. Positioning and leg exercises are discussed in Chapter 44 ∞ and anti-emboli stockings in Chapter 37 ∞. Sequential compression devices are an additional mechanical measure to help prevent venous stasis.

Sequential Compression Devices

Clients who are undergoing surgery or who are immobilized because of illness or injury or are in a critical care unit may benefit from sequential compression devices (SCDs) to promote venous return from the legs. Another term used in the literature is intermittent pneumatic

compression devices (IPCDs), and because there are different types of IPCDs, they are often collectively referred to as SCDs. SCDs are useful in preventing thrombi and edema, which may result from venous stasis, but they are not used for clients who have arterial insufficiency, cellulitis, infection of the extremity, active DVT, or preexisting venous thrombosis. SCDs inflate and deflate plastic sleeves to promote venous flow. The plastic sleeves are attached by tubing to an air pump that alternately inflates and deflates portions of the sleeve to a specified pressure.

SCDs are available in foot (sometimes called a foot pump or foot impulse device), knee-length, or thigh-length sleeves. The foot pump artificially stimulates the venous plantar plexus (a large vein located in the foot) to increase blood circulation in the foot. The inflation and deflation of the pump simulate the blood flow that results from walking. For the knee-length or thigh-length SCDs, the ankle area inflates first, followed by the calf region, and then the thigh area. This sequential inflation and deflation process assists the leg muscles in moving blood toward the heart (Figure 50.6 ■).

Foot, knee-high, and thigh-high SCDs are effective mechanical prophylaxis against VTEs if they are continuously worn. Unfortunately, research evidence shows that SCD therapy has either not been applied when it should have been, or has been incorrectly applied (Dunn & Ramos, 2017). This is problematic when it is the nurse's role to apply, maintain, and monitor SCD therapy. One barrier for nonadherance is that clients did not want to wear them because of discomfort, warmth, or sleep disruption. One study found that products that used "breathable" material were tolerated better by clients. It is important for the nurse to educate the client about the purpose and importance of the SCDs and to problem solve how to make them more comfortable (e.g., selecting SCD sleeves that fit properly).

Nurses must be attentive in their practice of applying and reapplying SCD devices after procedures, baths, and during chair activities (Dunn & Ramos, 2017, p. 166). The SCD is only removed for ambulation and is usually discontinued when the client resumes normal activity or is discharged.

Figure 50.6 ■ Sequential compression devices enhance venous return. They are available in foot, knee-high, or thigh-high versions.

Sequential compression therapy often goes together with other preventive measures. The client's risk level for DVT or PE often determines the preventive measures used. For example, clients at low risk may require only antiemboli stockings or ambulation. Clients at moderate risk may have both antiemboli stockings and sequential therapy, or low molecular weight heparin (LMWH) prophylaxis as part of their treatment (Crumley, 2018). The primary care provider may order antiemboli stockings, sequential therapy, and anticoagulation therapy for the high-risk client.

QSEN Patient-Centered Care: Sequential Compression Devices

A sequential compression device may be used in the home. Inform the client or caregiver how to apply the device correctly and how to operate the system, including how to respond to the alarm.

Skill 50.1 outlines how to apply a sequential compression device.

EVIDENCE-BASED PRACTICE

Evidence-Based Practice

Is There a Difference in Effectiveness and Safety of Different Intermittent Pneumatic Compression Devices (IPCDs) in the Prevention of VTE in Clients After Total Hip Replacement (THR)?

VTE is a common complication after a THR. Preventive measures commonly include prophylactic anticoagulation and IPCDs, or a combination of both. The IPCDs have a major advantage over anticoagulation in that they do not increase the risk of bleeding. A wide range of IPCDs are available. As a result, Andrews (2016) evaluated the effectiveness of different IPCDs after THR in order to inform clinical decision-making.

Andrews reviewed randomized controlled trials (RCTs) and quasi-randomized designs comparing different IPCDs for clients after THR for the prevention of VTE. One quasi-randomized trial met the inclusion criteria. This study consisted of 121 participants from a single medical center who had a THR. The participants were either in the calf–thigh pump intervention group or a plantar pump intervention group. All participants had the IPCD in place immediately after the THR for 4 hours per day for 21 days. A D-dimer blood level (for thrombogenesis) was measured before and after the THR. Postoperative swelling was measured by thigh and lower leg circumferences at 6 a.m. on the day of surgery and again at the same time on days 3, 7, 14, and 21. These measurements were compared to the preoperative measurements.

The results showed no cases of DVT or PE in either group during the first 3 weeks after the THR. The calf–thigh IPCD was more effective for reducing thigh swelling.

Implications

The author concluded that there was insufficient evidence for an informed choice of specific IPC device to use to prevent VTE after THR and that more research needs to be conducted. Andrews (2016) stressed the importance of nurses focusing on the risk–benefit ratio of the IPCD, applying the device correctly, and monitoring client adherence.

SKILL 50.1

Applying Sequential Compression Devices

PURPOSES

- To promote venous return from the legs
- To decrease risk of DVT and PE

ASSESSMENT

Assess for baseline data:

- Cardiovascular status, including heart rate and rhythm, peripheral pulses, and capillary refill
- Color and temperature of extremities
- Movement and sensation of feet and lower extremities

PLANNING

Check the primary care provider's order for type of SCD sleeve. **Rationale:** *Foot, knee- and thigh-length sleeves are available.*

- Read the manufacturer's directions for connecting and operating the compression controller.

Assignment

Assistive personnel (AP) often remove and reapply the SCD when performing hygiene care. The nurse should check that the AP knows the correct application process for the SCD. Remind the AP that the client should not have the SCD removed for long periods of time because the purpose of the SCD is to promote circulation. Remind AP to inspect the SCD sleeve and tubing each time prior to applying the sleeves.

Equipment

- Measuring tape
- SCD, including disposable sleeves, air pump, and tubing

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and the procedure for applying the sequential compression device. **Rationale:** *The client's participation and comfort will be increased by understanding the rationale for applying the SCD.*
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy and drape the client appropriately.
4. Prepare the client.
   - Place the client in a dorsal recumbent or semi-Fowler's position.
   - Measure the client's calf to determine sleeve size: medium (less than 21 in.), large (less than 26 in.), or extra-large (less than 32 in.) (Bartzak, 2018). Depending on the manufacturer, the thigh circumference may be needed to determine the size needed for a thigh-length sleeve.
5. Apply the sequential compression sleeves.
   - Place a sleeve under each leg with the opening at the knee.
   - Wrap the sleeve securely around the leg, securing the Velcro tabs. ❶ Allow two fingers to fit between the leg and the sleeve. **Rationale:** *This amount of space ensures that the sleeve does not impair circulation when inflated.*
6. Connect the sleeves to the control unit and adjust the pressure as needed.
   - Connect the tubing to the sleeves and control unit, ensuring that arrows on the plug and the connector are in alignment and that the tubing is not kinked or twisted. **Rationale:** *Improper alignment or obstruction of the tubing by kinks or twists will interfere with operation of the SCD.*
   - Turn on the control unit and adjust the alarms and pressures as needed. The sleeve cooling control and alarm should be on; ankle pressure is usually set at 35 to 55 mmHg. **Rationale:** *It is important to have the sleeve cooling control on for comfort and to reduce the risk of skin irritation from moisture under the sleeve. Proper pressure settings prevent injury to the client. Alarms warn of possible control unit malfunctions.*
7. Document the procedure.
   - Record baseline assessment data and application of the SCD. Note control unit settings.
   - Assess and document skin integrity and neurovascular and peripheral vascular status per agency policy while the SCD is in place. Remove the unit and notify the primary care provider if the client complains of numbness and tingling or leg pain. These may be symptoms of nerve compression.

❶ Applying a sequential compression device to the leg.

EVALUATION

- Perform appropriate follow-up assessments, such as peripheral vascular status including pedal pulses, skin color and temperature, skin integrity, and neurovascular status, including movement and sensation.
- Compare to the baseline data, if available.
- Report significant deviations from normal to the primary care provider.

LIFESPAN CONSIDERATIONS **Sequential Compression Devices**

CHILDREN

- Because young children tend to be more active, the SCD is rarely necessary unless the child is immobile (e.g., comatose).

OLDER ADULTS

- SCD sleeves may become loose as clients move around in bed. Check that the sleeves are secure and properly positioned.

DRUG CAPSULE

Low Molecular Weight Heparin: enoxaparin (Lovenox)

PREVENTION OF DEEP VEIN THROMBOSIS

The low molecular weight heparins are anticoagulants used to prevent deep vein thrombosis after hip, knee, or abdominal surgery. They are also used for clients at risk for thromboembolus secondary to prolonged bedrest due to acute illness. These heparins are given subcutaneously either once a day or every 12 hours. They have a predictable dose response and do not require daily laboratory test monitoring.

NURSING RESPONSIBILITIES

- Administration:
  - Administer deep subcutaneous. Do not give intramuscular.
  - Client should be lying down during administration.
  - Do not expel the air bubble from the prefilled syringe. This avoids loss of the drug.
  - The manufacturer recommends injection into the right or left anterior lateral or posterior lateral aspect of the abdominal wall for best absorption.
  - Alternate between right and left abdomen sites.
  - Insert the entire length of the needle into a skinfold created by the thumb and forefinger; hold the skinfold until the needle is withdrawn.
  - Do not massage the injection site to minimize bruising.
- Do not mix with other injections.
- Lovenox and regular heparin cannot be used interchangeably.
- Assess baseline lab data (e.g., CBC, liver function, coagulation) and monitor periodically.
- Observe for early signs and symptoms of bleeding.

CLIENT AND FAMILY TEACHING

- Review how to administer (see previous section).
- Administer at the same time each day.
- Report any unusual bleeding or bruising.
- Avoid aspirin or nonsteroidal anti-inflammatory drugs (NSAIDs).

Note: Prior to administering any medications, review all aspects with a current drug handbook or other reliable source.

Cardiopulmonary Resuscitation

Cardiopulmonary resuscitation (CPR) is a combination of oral resuscitation (mouth-to-mouth breathing or use of a mask), which supplies oxygen to the lungs, and external cardiac massage (chest compression), which is intended to reestablish cardiac function and blood circulation. CPR is also referred to as *basic life support (BLS).*

The AHA issues revised standards for CPR every 5 years (e.g., 2010, 2015). It covers all aspects of emergency cardiac care and simplifies CPR procedures so more healthcare professionals and lay rescuers might learn and perform them correctly. The complete guidelines are available online.

A cardiac arrest is the cessation of cardiac function; the heart stops beating. Often a cardiac arrest is unexpected and sudden. When it occurs, the heart no longer pumps blood to any of the organs of the body. Breathing then stops, and the individual becomes unconscious and limp. Within 20 to 40 seconds of a cardiac arrest, the victim is clinically dead. After 4 to 6 minutes, the lack of oxygen supply to the brain causes permanent and extensive damage.

The three cardinal signs of a cardiac arrest are apnea, absence of a carotid or femoral pulse, and dilated pupils. The individual's skin appears pale or grayish and feels cool. Cyanosis is evident when respiratory function fails before heart failure.

A respiratory arrest (pulmonary arrest) is the cessation of breathing. It often occurs because of a blocked airway, but it can occur following a cardiac arrest and for other reasons. A respiratory arrest may occur abruptly or be preceded by short, shallow breathing that becomes increasingly labored.

It is vital that all nurses be trained to perform CPR so resuscitation measures can be initiated immediately when a cardiac or respiratory arrest occurs. Nurses also can be instrumental in increasing community awareness of the need for CPR training and ensuring its availability.

Each healthcare facility has policies and procedures for announcing cardiac or respiratory arrest and initiating interventions, as well as a name by which this emergency is referred. Such emergencies are often referred to as a "code." There may be a button at the head of each bed for calling a code, an extension dialed on the phone, or a special phone used to announce the emergency. It is critical that each member of the client care team know the procedure for announcing this emergency. Calling the code summons the code team to the location of the emergency. The code team is made up of specially trained staff who can handle the emergency. Individuals are needed to perform rescue breathing, deliver chest compressions, administer medications, and make a record of the code activities. One staff member must be designated as the code leader—the individual who directs the activities of the other team members.

Some clients have requested via an advance directive that, should they arrest, they not be resuscitated. It is every individual's right to make an advance directive of his or her wishes, and a client's code status should always be documented, per agency policy, in the medical record (e.g., do not resuscitate [DNR]). Under most circumstances, if there is no DNR order in the record, all clients who arrest will have resuscitation efforts begun. *Both legally and ethically, there is no such thing as a "partial code," "slow code," or "mini code."*

Throughout any emergency situation, the nurse must remember the individual behind all of the technology. There is a client with spiritual and emotional needs who requires a personal connection. Holding a hand, making eye contact, talking directly to them—brief, seemingly small things make a huge difference to clients. To humanize healthcare is always a goal. Nursing *therapeutic presence* is the key. This should be extended to family members as well.

Evaluating

Using the overall goals identified in the planning stage, the nurse collects data to evaluate the effectiveness of interventions.

If desired outcomes are not achieved, the nurse, client, and support people if appropriate need to explore the reasons before modifying the care plan. For example, if the outcome "cardiac pump effectiveness" is not achieved, questions to be considered might include the following:

- Have other outcome measures for the goal of maintaining adequate cardiac output been met?
- Are prescribed medications being administered or taken as ordered?
- Are any additional factors placing stress on the heart?
- Is there a balance between factors that affect cardiac output, such as preload and afterload?
- Are there signs of fluid overload such as weight gain?

Critical Thinking Checkpoint

Mrs. Gloria Peterson reports that she is having increasing difficulty because she experiences severe pain in her calf muscles after walking for more than a city block. The pain subsides if she rests for a few minutes, but returns with activity. Her feet are cool and pale; pedal and posterior tibial pulses are not palpable, and femoral pulses are difficult to palpate. She lives in a downtown apartment and uses public transportation to travel across town to visit her husband's grave weekly.

1. What are the circulatory causes of her leg pain? Which risk factors would you expect to find in her history to support this conclusion?
2. Name two nursing diagnoses appropriate for Mrs. Peterson. Which would have the highest priority and why?
3. The primary care provider suggests that Mrs. Peterson cease her visits to the cemetery since she has to walk a long way there to reach the grave site. Would you agree with this plan? Why or why not? What considerations or viewpoints influence your choice?
4. Mrs. Peterson says that she wears antiemboli stockings because her friend told her they help the circulation in her legs. How would you respond to this information?

Answers to Critical Thinking Checkpoint questions are available on the faculty resources site. Please consult with your instructor.

Chapter 50 Review

CHAPTER HIGHLIGHTS

- The cardiovascular system transports gases in the blood to and from the tissues and facilitates the diffusion of gases between the capillaries and body tissues.
- The heart and the blood vessels make up the cardiovascular system. Together with blood, it is the major system for transporting oxygen and nutrients to the cells and removing wastes for disposal.
- The right side of the heart receives deoxygenated blood from the body and pumps it to the lungs via the pulmonary arteries; the left side receives oxygenated blood from the lungs and pumps it out to the body via the aorta.
- Coronary arteries supply oxygen and nutrients to the heart muscle.
- The cardiac cycle is made up of systolic and diastolic periods.
- The cardiac conduction system controls the electrical activity of the heart and the cardiac cycle: systole, contraction of the heart muscle and ejection of blood, and diastole, the relaxation period during which the heart fills with blood.
- Cardiac output depends on stroke volume, or the amount of blood ejected during systole, and heart rate.
- Systemic blood vessels carry blood to the tissues through a system of arteries, arterioles, and capillaries and return it to the heart through the venules, veins, and the venae cavae.
- Blood pressure rises gradually from birth to reach the adult range during adolescence.
- Atherosclerosis causes fatty plaque to develop within arteries.
- Decreased cardiac output, impaired tissue perfusion, and disorders affecting the blood are the major cardiovascular problems that affect oxygenation.
- Cardiac output may fall with a myocardial infarction (MI), heart failure, dysrhythmias, and structural alterations of the heart (e.g., valve deformities).
- The most common cause of impaired blood flow to organs and tissues is atherosclerosis; this can lead to tissue ischemia and pain.
- Cardiac monitoring is used for continuous observation of the heart rate and rhythm.
- Nursing interventions to promote circulation include using sequential compression devices to promote venous return from the legs, which prevents venous stasis.
- Cardiopulmonary resuscitation (CPR) is used during cardiopulmonary arrest. Each nurse needs to be aware of the hospital's policies and procedures regarding emergencies.

TEST YOUR KNOWLEDGE

1. The home health nurse has developed a teaching guide for a client with cardiovascular risk factors that focuses on the importance of regular physical activity with gradually increasing activity levels. This teaching guide specifically promotes which topic?
   1. Cardiac output and tissue perfusion
   2. Renal perfusion and formation of urine
   3. Oxygen-carrying capacity of white blood cells
   4. Effective breathing and airway clearance
2. The client's electrocardiogram (ECG) monitor reflects normal electrical activity through the heart's conduction system. The nurse knows that the electrical impulse travels in which sequence?
   1. Atrioventricular node
   2. Bundle branches
   3. Sinoatrial node
   4. Bundle of His
   5. Purkinje fibers

   Place the numbers in the correct sequence: _____
3. Which would most likely be included in the evaluation of the client goal of "Demonstrate adequate tissue perfusion"?
   1. Symmetrical chest expansion
   2. Use of pursed-lip breathing
   3. Brisk capillary refill
   4. Activity intolerance
4. A client is admitted with acute crushing chest pain that radiates down his left arm. The nurse expects which blood tests to be ordered for this client? Select all that apply.
   1. Blood urea nitrogen (BUN)
   2. Hemoglobin and hematocrit
   3. Creatine kinase (CK)
   4. Homocysteine level
   5. Troponin
5. Which client is most likely to experience poor cardiac output?
   1. A client who has recently completed exercising and is talking easily with an exercise partner
   2. A client who has a stroke volume of 70 mL per beat and a heart rate of 70 beats/min
   3. A client with a sustained heart rate of 150 beats/min
   4. A client who receives a positive inotropic medication
6. The nurse is assigned to three clients with the following diagnoses: myocardial infarction (MI), heart failure (HF), and anemia. In planning for their nursing care, the nurse knows that all three clients will have which sign or symptom?
   1. Pain
   2. Distended neck veins
   3. Shortness of breath
   4. Nausea
7. Which set of assessment data best validates that the nurse should initiate cardiopulmonary resuscitation on a comatose client?
   1. Cool, pale skin; unconsciousness; absence of radial pulse
   2. Cyanosis, slow pulse, dilated pupils
   3. Absent pulses, flushed skin, pinpoint pupils
   4. Apnea, absence of carotid or femoral pulses, dilated pupils
8. Which diagnoses would be most appropriate for clients with cardiovascular disease? Select all that apply.
   1. Impaired tissue perfusion
   2. Confusion
   3. Inadequate cardiac output
   4. Impaired sleep
   5. Inadequate physical energy for activities
9. The surgeon ordered sequential compression devices (SCDs) to be applied postoperatively. The client asks why the SCDs are needed. Which is the best response by the nurse when teaching the client about the purpose of SCDs?
   1. They promote arterial circulation.
   2. They promote venous return from the legs.
   3. They decrease afterload.
   4. They decrease postoperative pain.
10. A client with severe mitral stenosis is having surgery tomorrow. While teaching the client, the nurse shows the client a diagram of the heart. Identify with an "X" which valve the client will have replaced.

See Answers to Test Your Knowledge in Appendix A.

Fluid, Electrolyte, and Acid–Base Balance

51

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Discuss the function, distribution, composition, movement, and regulation of fluids and electrolytes in the body.
2. Describe the regulation of acid–base balance in the body, including the roles of buffers, the lungs, and the kidneys.
3. Identify factors affecting normal body fluid, electrolyte, and acid–base balance.
4. Discuss risk factors for, and causes and effects of, fluid, electrolyte, and acid–base imbalances.
5. Collect assessment data related to clients' fluid, electrolyte, and acid–base balances.
6. Identify examples of nursing diagnoses, outcomes, and interventions for clients with altered fluid, electrolyte, or acid–base balance.
7. Teach clients measures to maintain fluid and electrolyte balance.
8. Implement measures to correct imbalances of fluids, electrolytes, acids, and bases, such as enteral or parenteral replacements and blood transfusions.
9. Evaluate the effect of nursing and collaborative interventions on clients' fluid, electrolyte, or acid–base balance.
10. Verbalize the steps used in:
    a. Inserting a short peripheral catheter
    b. Monitoring an intravenous infusion
    c. Changing an intravenous container and tubing
    d. Discontinuing an intravenous infusion and removing a short peripheral catheter
    e. Changing a short peripheral catheter access to an intermittent infusion device
    f. Initiating, maintaining, and terminating a blood transfusion using a Y-set.
11. Recognize when it is appropriate to assign aspects of fluid, electrolyte, and acid–base balance to assistive personnel.
12. Demonstrate appropriate documentation and reporting of fluid, electrolyte, and acid–base balance activities.

Introduction

In good health, a delicate balance of fluids, electrolytes, acids, and bases maintains the body. This balance, or **homeostasis**, depends on multiple physiologic processes that regulate fluid intake and output, as well as the movement of water and the substances dissolved in it between body compartments.

Almost every illness has the potential to threaten this balance. Even in daily living, factors such as excessive temperatures or vigorous activity can affect homeostasis if adequate water and salt intake are not maintained. Therapeutic measures, such as the use of diuretics or nasogastric suction, can also disturb the body's homeostasis unless water and electrolytes are replaced.

Body Fluids and Electrolytes

The proportion of the human body composed of fluid is surprisingly large. Approximately 60% of the average healthy adult's weight is water, the primary body fluid. In good health this volume remains relatively constant, and an individual's weight varies by less than 0.2 kg (0.5 lb) in 24 hours, regardless of the amount of fluid ingested.

Age, sex, and body fat affect total body water. Infants have the highest proportion of water, accounting for 70% to 80% of their body weight. The proportion of body water decreases with age. In adults older than 60 years of age, it represents only about 50% of total body weight. Women generally have a lower percentage of body water than men. In both women and older adults, this is due to lower levels of muscle mass and a greater percentage of fat tissue. Fat tissue is essentially free of water, whereas lean tissue contains a significant amount of water. Therefore, water makes up a greater percentage of a lean individual's body weight than of an individual who is obese.

Distribution of Body Fluids

The body's fluid is divided into two major compartments, intracellular and extracellular. **Intracellular fluid (ICF)** is found within the cells of the body. It constitutes approximately two-thirds of the total body fluid in adults. **Extracellular fluid (ECF)** is found outside the cells and accounts for about one-third of total body fluid. ECF is further subdivided into compartments. The two main compartments of ECF are intravascular and interstitial. **Intravascular fluid**, or **plasma**, accounts for approximately 20% of ECF and is found within the vascular system. **Interstitial fluid**, accounting for approximately 75% of ECF, surrounds the cells (Figure 51.1 ■).

Intracellular fluid is vital to normal cell functioning. It contains solutes such as oxygen, electrolytes, and glucose, and it provides a medium in which metabolic processes of the cell take place.

Composition of Body Fluid

Extracellular and intracellular fluids contain oxygen from the lungs, dissolved nutrients from the gastrointestinal tract, excretory products of metabolism such as carbon dioxide, and charged particles called **ions**.

Many salts dissociate in water; that is, they break up into electrically charged ions. The salt called sodium chloride breaks up into one ion of sodium (Na^+) and one ion of chloride (Cl^-). These charged particles are called **electrolytes** because they are capable of conducting electricity. The number of ions that carry a positive charge, called **cations**, and ions that carry a negative charge, called **anions**, should be equal.

Figure 51.1 ■ Total body fluid represents 40 L in an adult male weighing 70 kg (154 lb).

Electrolytes generally are measured in milliequivalents per liter (mEq/L) or milligrams per 100 milliliters (mg/100 mL). The term **milliequivalent** refers to the chemical combining power of the ion, or the capacity of cations to combine with anions to form molecules, whereas the term *milligram* refers to the weight of the ion. Therefore, 1 mEq of any anion equals 1 mEq of any cation in terms of their capacity to combine into molecules. For example, sodium and chloride combine equally, so 1 mEq of Na^+ equals 1 mEq of Cl^-; however, a molecule of sodium is not equal in weight to a molecule of chloride.

Clinically, the milliequivalent system is most often used. However, nurses need to be aware that different systems of measurement may be found when interpreting laboratory results. For example, calcium levels frequently are reported in milligrams per deciliter (1 dL = 100 mL) instead of milliequivalents per liter.

The composition of fluids varies from one body compartment to another. In ECF, the principal electrolytes are sodium, chloride, and bicarbonate. Other electrolytes such as potassium, calcium, and magnesium are present, but in much smaller quantities. Plasma and interstitial fluid, the two primary components of ECF, contain essentially the same electrolytes and solutes, with the exception of protein. Plasma is a protein-rich fluid, containing large amounts of albumin, but interstitial fluid contains little or no protein.

The composition of ICF differs significantly from that of ECF. Potassium and magnesium are the primary cations present in ICF, and phosphate and sulfate are the major anions. As in ECF, other electrolytes are present within the cell, but in much smaller concentrations (Figure 51.2 ■).

Figure 51.2 ■ Electrolyte composition (cations and anions) of body fluid compartments.

F. H. MARTINI , J. L. NATH, and E. F. BARTHOLOMEW, FUNDAMENTALS OF ANATOMY & PHYSIOLOGY, 11th Ed., © 2018. Reprinted and Electronically reproduced by permission of Pearson Education, Inc., New York, NY.

Other body fluids such as gastric and intestinal secretions also contain electrolytes. This is of particular concern when these fluids are lost from the body (for example, in severe vomiting or diarrhea, or when gastric suction removes gastric secretions). Fluid and electrolyte imbalances can result from excessive losses through these routes.

Movement of Body Fluids and Electrolytes

The body fluid compartments are separated from one another by cell membranes and the capillary membrane. Although these membranes are completely permeable to water, they are considered to be **selectively permeable** to solutes, because substances other than water move across them with varying degrees of ease. Small particles such as ions, oxygen, and carbon dioxide move easily across these membranes, but larger molecules such as glucose and proteins have more difficulty moving between fluid compartments.

Solutes are substances dissolved in a liquid. Solutes may be **crystalloids** (salts that dissolve readily into true solutions) or **colloids** (substances such as large protein molecules that do not readily dissolve into true solutions). A **solvent** is the component of a solution that can dissolve a solute. In the body, water is the solvent; the solutes include electrolytes, gases such as oxygen and carbon dioxide, glucose, urea, amino acids, and proteins.

The concentration of solutes in body fluids is usually expressed as the **osmolality**. Osmolality is determined by the total solute concentration within a fluid compartment and is measured as parts of solute per kilogram of water.

Osmolality is reported as milliosmoles per kilogram (mOsm/kg). Sodium is by far the greatest determinant of the osmolality of plasma, or serum osmolality. The term *tonicity* may also be used to refer to the osmolality of one solution in relation to another solution. Solutions may be termed isotonic, hypertonic, or hypotonic. In relation to body fluids, an **isotonic** solution has the same osmolality as ECF. Normal saline, 0.9% sodium chloride, is an example of an isotonic solution. **Hypertonic** solutions, such as 3% sodium chloride, have a higher osmolality than ECF. **Hypotonic** solutions, such as 0.45% sodium chloride, have a lower osmolality than ECF. See Table 51.11 later in this chapter for additional information about intravenous (IV) solutions.

Osmotic pressure is the power of a solution to pull water across a semipermeable membrane. When two solutions of different concentrations are separated by a semipermeable membrane, the solution with the higher solute concentration exerts a higher osmotic pressure, pulling water across the membrane to equalize the concentrations of the solutions. In the body, plasma proteins also exert osmotic pressure called **colloid osmotic pressure** or **oncotic pressure**, holding water in plasma, and when necessary pulling water from the interstitial space into the vascular compartment. This is an important mechanism for maintaining vascular volume.

Figure 51.3 ■ Diffusion: the movement of molecules through a semipermeable membrane from an area of higher concentration to an area of lower concentration.

Figure 51.4 ■ Osmosis: the movement of water molecules from a less concentrated area to a more concentrated area in an attempt to equalize the concentration of solutions on two sides of a membrane.

The methods by which water and solutes move in the body are called diffusion, osmosis, filtration, and active transport. **Diffusion** occurs when two solutes of different concentrations are separated by a semipermeable membrane (Figure 51.3 ■). The rate of diffusion of a solute varies according to the size of the molecules, the concentration of the solution, and the temperature of the solution. **Osmosis** is a specific kind of diffusion in which *water* moves across cell membranes, from the less concentrated solution (the solution with less solute and more water) to the more concentrated solution (the solution with more solute and less water) (Figure 51.4 ■). In other words, water moves toward the higher concentration of solute in an attempt to equalize the concentrations of both water and solute.

Filtration is a process whereby fluid and solutes move together across a membrane from an area of higher pressure to an area of lower pressure. **Filtration pressure** is the pressure that results in the movement of the fluid and solutes out of a compartment. **Hydrostatic pressure** is the pressure exerted by a fluid within a closed system on the walls of the container in which it is held. The hydrostatic pressure of blood is the force exerted by blood against blood vessel walls. Osmotic pressure opposes and balances the force of hydrostatic pressure, and holds fluid in the vascular compartment to maintain the vascular volume. However, when hydrostatic pressure is greater than osmotic pressure, fluid filters out of the blood vessels. Filtration pressure is the difference between the hydrostatic pressure and the osmotic pressure (Figure 51.5 ■). **Active transport** is the movement of solutes across cell membranes from a less concentrated solution to a more concentrated one. This process differs from diffusion and osmosis, which are passive processes, in that metabolic energy is expended.

Regulating Body Fluids

In a healthy individual, the volumes and chemical composition of the fluid compartments stay within specific and narrow limits. Normally, fluid intake and fluid loss are balanced. Illness can upset this balance so that the body has too little or too much fluid.

Fluid Intake

During periods of normal activity at moderate temperature, the average adult drinks about 1200 to 1500 mL/day, despite the fact that adults need 2500 mL/day for normal functioning. The additional 1000-mL volume is acquired from foods and from the oxidation of these foods during metabolic processes. The water content of food is relatively large, contributing about 1000 mL/day. Water as a by-product of food metabolism accounts for most of the remaining fluid volume required. This quantity is approximately 200 mL/day for the average adult (Table 51.1).

Figure 51.5 ■ Schematic of filtration pressure changes within a capillary bed. On the arterial side, arterial blood pressure exceeds colloid osmotic pressure, so that water and dissolved substances move out of the capillary into the interstitial space. On the venous side, venous blood pressure is less than colloid osmotic pressure, so that water and dissolved substances move into the capillary.

TABLE 51.1 Average Daily Fluid Intake for an Adult

Source	Amount (mL)
Oral fluids	1200–1500
Water in foods	1000
Water as by-product of food metabolism	200
Total	2400–2700

The thirst mechanism is the primary regulator of fluid intake. The thirst center is located in the hypothalamus of the brain. A number of stimuli trigger the thirst center, including the osmotic pressure of body fluids, vascular volume, and angiotensin (a hormone released in response to decreased blood flow to the kidneys), causing the sensation of thirst and the desire to drink fluids.

Thirst is normally relieved immediately after drinking a small amount of fluid, when the ingested fluid distends the upper gastrointestinal tract, but before the fluid is actually absorbed from the gastrointestinal tract. However, this relief is only temporary, and thirst returns in about 15 minutes. The thirst is again temporarily relieved by drinking a small amount of fluid. This mechanism protects the individual from drinking too much, because it takes between 30 minutes and 1 hour for fluid to be absorbed and distributed throughout the body.

Fluid Output

Fluid losses from the body counterbalance the intake of fluid, as shown in Table 51.2. Urine is formed by the kidneys and excreted from the urinary bladder, and is the major route of fluid output. Normal urine output for an adult is 1400 to 1500 mL per 24 hours, or at least 0.5 mL per kilogram per hour.

The chyme that passes from the small intestine into the large intestine contains both water and electrolytes. The volume of chyme entering the large intestine in an adult is normally about 1500 mL/day. Of this amount, all but about 100 mL is reabsorbed in the proximal half of the large intestine. The reabsorbed volume contains primarily water and electrolytes.

Insensible fluid losses occur through the skin and the lungs. They are called insensible because it is usually not noticeable and cannot be measured. Insensible fluid loss through the skin occurs in two ways, diffusion and perspiration. Water loss through the skin is not noticeable but normally accounts for 350 to 400 mL/day. Another type of insensible loss is the water in exhaled air. In an adult, this is normally 350 to 400 mL/day.

TABLE 51.2 Average Daily Fluid Output for an Adult

Route	Amount (mL)
Urine	1400–1500
Insensible losses	
Lungs	350–400
Skin	350–400
Sweat	100
Feces	100–200
Total	2300–2600

Maintaining Homeostasis

The volume and composition of body fluids are regulated through several homeostatic mechanisms. A number of organs and systems contribute to this regulation, including the kidneys, lungs, and the cardiovascular and gastrointestinal systems. Hormones such as antidiuretic hormone, the renin-angiotensin-aldosterone system, and atrial natriuretic factor are also involved, as are mechanisms to monitor and maintain vascular volume.

The kidneys are the primary regulator of body fluids and electrolyte balance. They regulate the volume and osmolality of ECF by regulating water and electrolyte excretion. The kidneys control the reabsorption of water from plasma filtrate and ultimately the amount excreted as urine. Electrolyte balance is maintained by selective retention and excretion by the kidneys. The kidneys also play a significant role in acid–base regulation, excreting hydrogen ion (H^+) and retaining bicarbonate.

Several neuroendocrine control mechanisms help control fluid and electrolyte balance. The antidiuretic hormone (ADH) regulates water excretion from the kidney, is synthesized in the anterior portion of the hypothalamus, and acts on the collecting ducts of the nephrons. When serum osmolality rises, ADH is produced, causing the collecting ducts to become more permeable to water. This increased permeability allows more water to be reabsorbed into the blood. As more water is reabsorbed, urine output falls and serum osmolality decreases because the water dilutes body fluids. Conversely, if serum osmolality decreases, ADH is suppressed, the collecting ducts become less permeable to water, and urine output increases. Excess water is excreted, and serum osmolality returns to normal (Figure 51.6 ■).

Specialized receptors in the kidneys respond to changes in renal perfusion, stimulating the **renin-angiotensin-aldosterone system**. If blood flow or pressure to the kidney decreases, renin is released. Renin causes the conversion of angiotensinogen to angiotensin I, which is then converted to angiotensin II by angiotensin-converting enzyme. Angiotensin II acts directly on the nephrons to promote sodium and water retention. In addition, it stimulates the release of aldosterone from the adrenal cortex. Aldosterone also promotes sodium retention in the distal nephron. The net effect of the renin-angiotensin-aldosterone system is to increase blood volume (and renal perfusion) through sodium and water retention.

The atrial natriuretic factor (ANF) is released from cells in the atrium of the heart in response to excess blood volume and stretching of the atrial walls. Acting on the nephrons, ANF promotes sodium wasting and acts as a

Figure 51.6 ■ Antidiuretic hormone (ADH) regulates water excretion from the kidneys.

potent diuretic, thus decreasing blood volume. ANF also inhibits thirst, reducing fluid intake.

Regulating Electrolytes

Electrolytes, charged ions capable of conducting electricity, are present in all body fluids and fluid compartments. Just as maintaining fluid balance is vital to normal body functioning, so is maintaining electrolyte balance. Although the concentration of specific electrolytes differs between fluid compartments, a balance of cations (positively charged ions) and anions (negatively charged ions) always exists. Electrolytes are important for:

- Maintaining fluid balance
- Contributing to acid–base regulation
- Facilitating enzyme reactions
- Transmitting neuromuscular reactions.

Most electrolytes enter the body through dietary intake and are excreted in the urine. Some electrolytes, such as sodium chloride and potassium, are not stored by the body and must be consumed daily to maintain normal levels. Other electrolytes, such as calcium, are stored in the body; when serum levels drop, ions can shift out of storage into the blood to maintain adequate serum levels for normal functioning, at least in the short term. The regulatory mechanisms and functions of the major electrolytes are summarized in Table 51.3.

Sodium

Sodium (Na^+) is the most abundant cation in ECF and a major contributor to serum osmolality. Normal serum sodium levels are 135 to 145 mEq/L. Sodium functions largely in controlling and regulating water balance. Sodium is found in many foods (Table 51.4).

TABLE 51.3 Regulation and Functions of Electrolytes

Electrolyte	Regulation	Function
Sodium (Na^+)	• Renal reabsorption or excretion • Aldosterone increases Na^+ reabsorption in collecting duct of nephrons	• Regulating ECF volume and distribution • Maintaining blood volume • Transmitting nerve impulses and contracting muscles
Potassium (K^+)	• Renal excretion • Aldosterone increases K^+ excretion • Movement into and out of cells • Insulin helps move K^+ into cells; tissue damage and acidosis shift K^+ out of cells into ECF	• Maintaining ICF osmolality • Transmitting nerve and other electrical impulses • Regulating cardiac impulse transmission and muscle contraction • Skeletal and smooth muscle function • Regulating acid–base balance
Calcium (Ca^{2+})	• Redistribution between bones and ECF • Parathyroid hormone and calcitriol increase serum Ca^{2+} levels; calcitonin decreases serum levels	• Forming bones and teeth • Transmitting nerve impulses • Regulating muscle contractions • Maintaining cardiac pacemaker (automaticity) • Blood clotting
Magnesium (Mg^{2+})	• Conservation and excretion by kidneys • Intestinal absorption increased by vitamin D and parathyroid hormone	• Intracellular metabolism • Operating sodium–potassium pump • Relaxing muscle contractions • Transmitting nerve impulses • Regulating cardiac function
Chloride (Cl^-)	• Excreted and reabsorbed along with sodium in the kidneys • Aldosterone increases chloride reabsorption with sodium	• HCl production • Regulating ECF balance and vascular volume • Regulating acid–base balance • Buffer in oxygen–carbon dioxide exchange in RBCs
Phosphate (PO_4^{3-})	• Excretion and reabsorption along with sodium in the kidneys • Parathyroid hormone decreases serum levels by increasing renal excretion • Reciprocal relationship with calcium: increasing serum calcium decreases phosphate levels; decreasing serum calcium increases phosphate	• Forming bones and teeth • Metabolizing carbohydrate, protein, and fat • Cellular metabolism; producing ATP and DNA • Muscle, nerve, and RBC function • Regulating acid–base balance • Regulating calcium levels
Bicarbonate (HCO_3^-)	• Excretion and reabsorption by the kidneys • Regeneration by kidneys	• Major body buffer involved in acid–base regulation

TABLE 51.4 Electrolyte-Rich Foods

Electrolyte	Vegetables	Fruits	Meats and Fish	Beverages	Other
Sodium	Dried, canned, pickled or brined vegetables, seaweeds	Dried, canned, pickled, or brined	Bacon, cold cuts, cured meats	Chocolate milk	Canned soups, processed cheese, cereal, table salt
Potassium	Raw carrots, baked potatoes, spinach, raw tomatoes	Avocados, bananas, dried fruits, apricots, cantaloupe, oranges	Beef, cod, pork, veal	Milk, orange juice, coconut water	Nuts
Calcium	Kale, broccoli, watercress, bok choy, okra	Oranges, dried apricots, dates, rhubarb, kiwi	Sardines, salmon	Milk	Yogurt, kefir, almonds, tofu
Magnesium	Dark leafy greens, beans and lentils	Avocados, bananas, dried fruits	Mackerel, tuna, turbot	Coffee, chocolate syrup prepared with milk	Nuts, seeds, whole grains, dark chocolate
Phosphate	Legumes	Spinach, butternut squash, okra	Fish, beef, turkey, chicken	Milk	Nuts, yogurt, whole grains

Potassium

Potassium (K^+) is the major cation in ICF, with only a small amount found in the ECF. ICF levels of potassium are usually 125 to 140 mEq/L, while normal serum potassium levels are 3.5 to 5.0 mEq/L. The ratio of intracellular to extracellular potassium must be maintained for neuromuscular response to stimuli. Potassium is a vital electrolyte for skeletal, cardiac, and smooth muscle activity. It is also involved in maintaining acid–base balance, and it contributes to intracellular enzyme reactions. Potassium must be ingested daily because the body cannot conserve it. See Table 51.4 for foods containing potassium.

Calcium

The vast majority (99%) of calcium (Ca^{2+}) in the body is stored in the skeletal system, with a relatively small amount in extracellular fluid. Although the calcium outside the bones and teeth amounts to only about 1% of the total calcium in the body, it is vital in regulating neuromuscular function, including muscle contraction and relaxation, as well as cardiac function. ECF calcium is regulated by a complex interaction of parathyroid hormone, calcitonin (a hormone produced by the thyroid), and calcitriol (a metabolite of vitamin D). When calcium levels in the ECF fall, parathyroid hormone and calcitriol cause calcium to be released from bones into ECF and increase the absorption of calcium in the intestines, thus raising serum calcium levels. Conversely, calcitonin stimulates the deposition of calcium in bone, reducing the concentration of calcium ions in the blood.

With increasing age, the intestines absorb calcium less effectively, and more calcium is excreted by the kidneys. Calcium shifts out of the bone to replace these ECF losses, increasing the risk of osteoporosis and fractures of the wrists, vertebrae, and hips. Lack of weight-bearing exercise (which helps keep calcium in the bones) and a vitamin D deficiency contribute to this risk, as do genetics and lifestyle factors. See Table 51.4 for foods containing calcium.

Serum calcium levels are often reported in two ways, based on the way it is circulating in the plasma. Approximately 50% of serum calcium circulates in a free, or unbound, form. The other 50% circulates bound to either plasma proteins or other nonprotein ions. The total serum calcium level (normal range: 8.5 to 10.5 mg/dL) represents both bound and unbound calcium. The ionized serum calcium level (normal range: 4.0 to 5.0 mg/dL) represents free, or unbound, calcium.

Magnesium

Magnesium (Mg^{2+}) is found primarily in the skeleton and ICF, where it is the second most abundant intracellular cation. It is important for intracellular metabolism, and for protein and DNA synthesis within the cells. Only about 1% of the body's magnesium is in ECF, and it has a normal serum level of 1.5 to 2.5 mEq/L. In ECF it is involved in regulating neuromuscular and cardiac function. Maintaining and ensuring adequate magnesium levels is an important part of the care of clients with cardiac disorders. See Table 51.4 for foods high in magnesium.

Chloride

Chloride (Cl^-) is the major anion of ECF, and normal serum levels are 95 to 108 mEq/L. Chloride functions with sodium to regulate serum osmolality and blood volume. The concentration of chloride in ECF is regulated secondarily to sodium; when sodium is reabsorbed in the kidney, chloride usually follows. Chloride is a major component of gastric juice as hydrochloric acid (HCl) and is involved in regulating acid–base balance. It also acts as a buffer in the exchange of oxygen and carbon dioxide in red blood cells (RBCs). Chloride is found in the same foods as sodium.

Phosphate

Phosphate (PO_4^{3-}) is the major anion of ICF. It also is found in ECF, bone, skeletal muscle, and nerve tissue. Normal serum levels of phosphate in adults range from 2.5 to 4.5 mg/dL. Phosphate is involved in many chemical actions of cells, and is essential for functioning of muscles, nerves, and RBCs. It is also involved in the metabolism of protein, fat, and carbohydrate. Phosphate is absorbed from the intestine and is found in many foods (see Table 51.4).

Bicarbonate

Bicarbonate (HCO_3^-) is present in both ICF and ECF. Its primary function is regulating acid–base balance as an essential component of the body's buffering system. The kidneys regulate extracellular bicarbonate levels. Bicarbonate is excreted when too much is present; if more is needed, the kidneys both regenerate and reabsorb bicarbonate ions. Unlike electrolytes that must be consumed in the diet, adequate amounts of bicarbonate are produced through metabolic processes.

Acid–Base Balance

An important part of regulating the homeostasis of body fluids is regulating their acidity and alkalinity. An **acid** is a substance that releases hydrogen ions (H^+) in solution. **Bases**, or alkalis, have a low hydrogen ion concentration and can accept hydrogen ions in solution. The relative acidity or alkalinity of a solution is measured by its **pH**, which is an inverse reflection of the hydrogen ion concentration of the solution. The higher the hydrogen ion concentration, the lower the pH; the lower the hydrogen ion concentration, the higher the pH. Water has a pH of 7 and is neutral. Solutions with a pH lower than 7 are acidic; those with a pH higher than 7 are alkaline.

Regulation of Acid–Base Balance

Body fluids are normally maintained within a narrow range that is slightly alkaline. The normal pH of arterial blood is between 7.35 and 7.45 (Figure 51.7 ■). Acids are continually produced during metabolism. Several body systems, including the respiratory and renal systems, and buffers are actively involved in maintaining the narrow pH range necessary for optimal functioning. Buffers help maintain acid–base balance by neutralizing excess acids or bases.

Figure 51.7 ■ Body fluids are normally slightly alkaline, between a pH of 7.35 and 7.45.

The lungs and the kidneys help maintain a normal pH by either excreting or retaining acids and bases as needed.

Buffers

Buffers prevent excessive changes in pH by binding with or releasing hydrogen ions. If body fluids become too acidic, meaning excess hydrogen ions are present in body fluids, buffers bind with the hydrogen ions. If body fluids become too alkaline, meaning not enough hydrogen ions are present in body fluids, buffers can release hydrogen ions. The action of a buffer is immediate, but limited in its capacity to maintain or restore normal acid–base balance.

The major buffer in ECF is the bicarbonate (HCO_3^-) and carbonic acid (H_2CO_3) system. The amounts of bicarbonate and carbonic acid in the body vary; however, as long as a ratio of 20 parts of bicarbonate to 1 part of carbonic acid is maintained, the pH remains within its normal range of 7.35 to 7.45. However, adding a strong acid to ECF can change this ratio because bicarbonate is depleted in neutralizing the acid. When this happens, the pH drops, and the client has a condition called **acidosis**. The ratio can also be upset by adding a strong base to ECF, depleting carbonic acid as it combines with the base. In this case the pH rises and the client has **alkalosis**.

Respiratory Regulation

The lungs help regulate acid–base balance by eliminating or retaining carbon dioxide (CO_2). When combined with water, carbon dioxide forms carbonic acid ($CO_2 + H_2O = H_2CO_3$). This chemical reaction is reversible; carbonic acid breaks down into carbon dioxide and water. The lungs help regulate acid–base balance by altering the rate and depth of respirations. The response of the respiratory system to changes in pH is rapid, occurring within minutes. Carbon dioxide levels in the blood are measured as PCO_2, the partial pressure of the dissolved CO_2 in venous blood, and $PaCO_2$, the partial pressure of the dissolved CO_2 in arterial blood. Normal $PaCO_2$ is 35 to 45 mmHg.

Renal Regulation

Although buffers and the respiratory system can compensate for changes in pH, the kidneys are the ultimate long-term regulator of acid–base balance. They are slower to respond to changes, requiring hours to days to correct imbalances, but their response is more permanent and selective than that of the other systems. The kidneys maintain acid–base balance by selectively excreting or conserving bicarbonate and hydrogen ions. The normal serum bicarbonate level is 22 to 26 mEq/L. The relationship between respiratory and renal regulation of acid–base balance is further explained in Box 51.1.

BOX 51.1 Physiologic Regulation of Acid–Base Balance

Lungs				Kidneys
$CO_2 + H_2O$	↔	H_2CO_3	↔	$H + HCO_3$
Carbon dioxide + Water		Carbonic acid		Hydrogen + bicarbonate

The lungs and kidneys are the two major systems that work on a continuous basis to help regulate the acid–base balance in the body. In the aforementioned biochemical reactions, the processes are all reversible and go back and forth as the body's needs change. The lungs can work very quickly and do their part by either retaining or getting rid of carbon dioxide by changing the rate and depth of respirations. The kidneys work much more slowly; they may take hours to days to regulate the balance by either excreting or conserving hydrogen and bicarbonate ions. Under normal conditions, the two systems work together to maintain homeostasis.

Factors Affecting Body Fluid, Electrolytes, and Acid–Base Balance

The ability of the body to adjust fluids, electrolytes, and acid–base balance is influenced by age, sex and body size, environmental temperature, and lifestyle.

Age

Infants and growing children have much greater fluid turnover than adults because their higher metabolic rate increases fluid loss. Infants lose more fluid through the kidneys because immature kidneys are less able to conserve water than adult kidneys. In addition, infants' respiratory rate is much higher than that of adults, and their body surface area is proportionately greater than that of adults, both of which increases insensible fluid losses. This higher turnover of fluid, combined with the losses produced by disease, can create critical fluid imbalances in children much more rapidly than in adults.

In older individuals, the normal aging process may affect fluid balance. The thirst response is often diminished. Antidiuretic hormone levels remain normal or may even be elevated, but the nephrons become less able to conserve water in response to ADH. Higher levels of

LIFESPAN CONSIDERATIONS **Fluid and Electrolyte Imbalance**

INFANTS AND CHILDREN

Infants are at high risk for fluid and electrolyte imbalance because:

- Their immature kidneys cannot concentrate urine.
- They have a rapid respiratory rate and proportionately larger body surface area than adults, leading to greater insensible losses through the skin and respirations.
- They cannot express thirst, nor actively seek fluids.

Vomiting and diarrhea in infants and young children can lead quickly to electrolyte imbalance. Oral rehydration therapy (ORT) with electrolyte solutions such as Pedialyte should be used to restore fluid and electrolyte balance in mild to moderate dehydration. Prompt treatment with ORT can prevent the need for IV therapy and hospitalization. Even if the child is vomiting, small sips of an ORT solution can be helpful.

OLDER ADULTS

Older adults are at high risk for fluid and electrolyte imbalance because of *decreases* in:

- Thirst sensation
- Ability of the kidneys to concentrate urine
- Intracellular fluid and total body water
- Response to body hormones that help regulate fluid and electrolytes.

Other factors that may influence fluid and electrolyte balance in older adults are:

- Use of diuretics for hypertension and heart disease
- Decreased intake of food and water, especially in older adults with dementia or who are dependent on others to feed them and offer them fluids
- Preparations for diagnostic tests that include being NPO for long periods of time, laxatives, or contrast dyes
- Impaired renal function, for example, in older adults with diabetes.

All of these conditions increase older adults' risk for fluid and electrolyte imbalance, particularly under conditions that challenge the normal compensatory mechanisms, such as a fever, influenza, surgery, or heat exposure. The change can happen quickly and become serious in a short time. Smart observations and quick actions by the nurse can help prevent serious consequences. A change in mental status may be the first symptom of impairment and must be further evaluated to determine the cause.

atrial natriuretic factor in older adults may also contribute to this impaired ability to conserve water. These normal changes of aging increase the risk of dehydration. When combined with the increased likelihood of heart diseases, impaired renal function, and multiple drug regimens, the older adult's risk for fluid and electrolyte imbalance is significant.

Sex and Body Size

Total body water also is affected by sex and body size. Fat cells contain little or no water, but lean muscle tissue has a high water content; therefore, individuals with a higher percentage of body fat have less body water than individuals with a higher percentage of lean muscle. Women generally have proportionately more body fat and, therefore, less body water than men.

Environmental Temperature

Individuals with an illness and those participating in strenuous activity are at increased risk for fluid and electrolyte imbalances when the environmental temperature is high. Fluid losses through sweating are increased in hot environments as the body attempts to disperse heat. These losses are even greater in individuals who are not accustomed to a hot environment.

Both electrolytes and water are lost through sweating. When only water is replaced, electrolyte depletion is a risk. An individual who is electrolyte depleted may experience fatigue, weakness, headache, and gastrointestinal symptoms such as anorexia and nausea. The risk of adverse effects is even greater if lost water is not replaced. Body temperature rises, and the individual is at risk for heat exhaustion or heatstroke; this happens when an individual's heat production exceeds the body's ability to dissipate heat. Consuming adequate amounts of cool liquids, particularly during strenuous activity, reduces the risk of adverse effects from heat. Balanced electrolyte solutions and carbohydrate-electrolyte solutions such as sports drinks are recommended because they replace both water and electrolytes lost through perspiration.

Lifestyle

Lifestyle factors such as diet, exercise, stress, and alcohol consumption affect fluid, electrolyte, and acid–base balance.

Intake of fluids and electrolytes is affected by diet. Individuals with anorexia nervosa or bulimia are at risk for severe fluid and electrolyte imbalances because of inadequate intake or purging regimens (e.g., induced vomiting, use of diuretics and laxatives). Seriously malnourished individuals have decreased serum protein levels, and may develop edema because serum osmotic pressure is reduced. When calorie intake is not adequate to meet the body's needs, fat stores are broken down and fatty acids are released, increasing the risk of acidosis.

Regular weight-bearing exercise such as walking or running has a beneficial effect on calcium balance. The rate of bone loss that occurs in postmenopausal women and older men is slowed with weight-bearing exercise, reducing the risk of osteoporosis.

Stress can increase cellular metabolism, blood glucose concentration, and catecholamine levels. In addition, stress can increase production of ADH and stimulate the renin-angiotensin-aldosterone system, both of which decrease urine production. The overall response of the body to stress is to increase blood volume.

Heavy alcohol consumption increases the risk of low calcium, magnesium, and phosphate levels. Individuals who drink large amounts of alcohol are also at risk for acidosis associated with breakdown of fat tissue.

Disturbances in Fluid Volume, Electrolyte, and Acid–Base Balances

A number of factors such as illness, trauma, surgery, and medications can affect the body's ability to maintain fluid, electrolyte, and acid–base balance. The kidneys play a major role in maintaining fluid, electrolyte, and acid–base balances, and renal disease is a significant cause of imbalances. In addition, decreased blood flow to the kidneys due to cardiovascular disease stimulates the renin-angiotensin-aldosterone system, causing sodium and water retention. Diseases such as diabetes mellitus, cancer, and chronic obstructive lung disease may affect acid–base balance. Clients who are confused or unable to communicate their needs are at risk for inadequate fluid intake. Vomiting, diarrhea, or nasogastric suction can cause significant fluid losses. Tissue trauma, such as burns, causes fluid and electrolytes to be lost from damaged cells. Medications such as diuretics or corticosteroids can result in abnormal losses of electrolytes and fluid loss or retention.

Fluid Imbalances

Fluid imbalances are of two basic types: isotonic and osmolar. Isotonic imbalances occur when water and electrolytes are lost or gained in equal proportions, so that the osmolality of body fluids remains constant. Osmolar imbalances involve the loss or gain of only water, so that the osmolality of the serum is altered. Thus, four categories of fluid imbalances may occur: (1) an isotonic loss of water and electrolytes, (2) an isotonic gain of water and electrolytes, (3) a hyperosmolar loss of only water, and (4) a hypo-osmolar gain of only water. These are referred to, respectively, as fluid volume deficit, fluid volume excess, dehydration (hyperosmolar imbalance), and overhydration (hypo-osmolar imbalance).

Fluid Volume Deficit

Isotonic **fluid volume deficit (FVD)** occurs when the body loses both water and electrolytes from the ECF in similar proportions. Thus, the decreased volume of fluid remains isotonic. In FVD, fluid is initially lost from the intravascular compartment, so it often is called **hypovolemia**.

FVD generally occurs as a result of (a) abnormal losses through the skin, gastrointestinal tract, or kidney; (b) decreased intake of fluid; (c) bleeding; or (d) movement of fluid into a third space. See the section on third space syndrome that follows.

For the risk factors and clinical signs related to FVD, see Table 51.5.

THIRD SPACE SYNDROME

In **third space syndrome**, fluid shifts from the vascular space into an area where it is not readily accessible as extracellular fluid. This fluid remains in the body but is essentially unavailable for use, causing an isotonic fluid volume deficit. Fluid may be isolated in the bowel, in injured tissue (e.g., severe burns), or in potential spaces such as the peritoneal or pleural cavities.

Third spacing has two distinct phases: loss and reabsorption. The client with third space syndrome during the loss phase has an isotonic fluid deficit. During the reabsorption phase, tissues begin to heal and fluid moves back into the intravascular space. Careful nursing assessment is vital to effectively identify and intervene for clients experiencing third spacing. Because fluid shifts from the vascular compartment (loss phase) and then back into the vascular compartment after time (reabsorption phase), assessment for manifestations of fluid volume deficit and excess is vital.

TABLE 51.5 Isotonic Fluid Volume Deficit

Risk Factors	Clinical Manifestations	Nursing Interventions
Loss of water and electrolytes from: • Vomiting • Diarrhea • Excessive sweating • Polyuria • Fever • Nasogastric suction • Abnormal drainage or wound losses Insufficient intake due to: • Anorexia • Nausea • Inability to access fluids • Impaired swallowing • Confusion, depression	Complaints of weakness and thirst Weight loss: • 2% loss = mild FVD • 5% loss = moderate • 8% loss = severe Fluid intake less than output Decreased tissue turgor Dry mucous membranes, sunken eyeballs, decreased tearing Subnormal temperature Weak pulse; tachycardia Decreased blood pressure Postural (orthostatic) hypotension (significant drop in BP when moving from lying to sitting or standing position) Decreased capillary refill Decreased central venous pressure Decreased urine volume (<30 mL/hr) Increased specific gravity of urine (>1.030) Increased hematocrit Increased blood urea nitrogen (BUN)	Assess for clinical manifestations of FVD. Monitor weight and vital signs, including temperature. Assess tissue turgor. Monitor fluid intake and output. Monitor laboratory findings. Administer oral and IV fluids as indicated. Provide frequent mouth care. Implement measures to prevent skin breakdown. Provide for safety (e.g., provide assistance for a client rising from bed or chair).

Fluid Volume Excess

Fluid volume excess (FVE) occurs when the body retains both water and sodium in similar proportions to normal ECF. This is commonly referred to as **hypervolemia** (increased blood volume). FVE is always secondary to an increase in the total body sodium content, which leads to an increase in total body water. Because both water and sodium are retained, the serum sodium concentration remains essentially normal and the excess volume of fluid is isotonic. Specific causes of FVE include (a) excessive intake of sodium chloride; (b) administering sodium-containing infusions too rapidly, particularly to clients with impaired regulatory mechanisms; and (c) disease processes that alter regulatory mechanisms, such as heart failure, renal failure, cirrhosis of the liver, and Cushing's syndrome.

The risk factors and clinical manifestations for FVE are summarized in Table 51.6.

EDEMA

In fluid volume excess, both intravascular and interstitial spaces have an increased water and sodium content. Excess interstitial fluid is known as edema. Edema typically is most apparent in areas where the tissue pressure is low, such as around the eyes, and in dependent tissues (known as dependent edema), where hydrostatic capillary pressure is high (Figure 51.8 ■).

Pitting edema is edema that leaves a small depression or pit after finger pressure is applied to the swollen area. The pit is caused by movement of fluid to adjacent tissue, away from the point of pressure (Figure 51.9 ■). Within 10 to 30 seconds the pit normally disappears as fluid returns to the area.

Dehydration

Dehydration, or a hyperosmolar fluid imbalance, occurs when water is lost from the body, leaving the client with excess sodium. Because water is lost while electrolytes, particularly sodium, are retained, serum osmolality and serum sodium levels increase. Water is drawn into the vascular compartment from the interstitial space and cells, resulting in cellular dehydration. Older adults are at particular risk for dehydration because of decreased thirst sensation. Dehydration can also affect clients who are hyperventilating, have a prolonged fever, are in diabetic ketoacidosis, or are receiving enteral feedings with insufficient water intake.

Figure 51.8 ■ Dependent pedal edema.
Amawasri Pakdara/123RF.

Overhydration

Overhydration, or a hypo-osmolar fluid imbalance, occurs when water is gained in excess of electrolytes, resulting in low serum osmolality and low serum sodium levels. Water is drawn into the cells, causing them to swell. In the brain, this can lead to cerebral edema and impaired neurologic function. Overhydration, sometimes called water intoxication, often occurs when both fluid and electrolytes are lost, for example, through excessive sweating, but only water is replaced. It can also result from the syndrome of inappropriate antidiuretic hormone (SIADH), a disorder that can occur with some malignant tumors, AIDS, head injury, or administration of certain drugs such as barbiturates or anesthetics.

Electrolyte Imbalances

The most common and clinically significant electrolyte imbalances involve sodium, potassium, calcium, magnesium, chloride, and phosphate.

TABLE 51.6 Isotonic Fluid Volume Excess

Risk Factors	Clinical Manifestations	Nursing Interventions
Excess intake of sodium-containing IV fluids Excess ingestion of sodium in diet or medications (e.g., sodium bicarbonate antacids such as Alka-Seltzer or hypertonic enema solutions such as Fleet's) Impaired fluid balance regulation related to: • Heart failure • Renal failure • Cirrhosis of the liver	Weight gain: • 2% gain = mild FVE • 5% gain = moderate • 8% gain = severe Fluid intake greater than output Full, bounding pulse; tachycardia Increased blood pressure and central venous pressure Distended neck veins Moist crackles (rales) in lungs; dyspnea, shortness of breath Mental confusion	Assess for clinical manifestations of FVE. Monitor weight and vital signs. Assess for edema. Assess breath sounds. Monitor fluid intake and output. Monitor laboratory findings. Place in Fowler's position. Administer diuretics as ordered. Restrict fluid intake as indicated. Restrict dietary sodium as ordered. Implement measures to prevent skin breakdown.

A B

Figure 51.9 ■ Evaluation of edema. *A*, Palpate for edema over the tibia as shown here and behind the medial malleolus, and over the dorsum of each foot. *B*, Four-point scale for grading edema.

Sodium

Sodium (Na^+), the most abundant cation in the extracellular fluid, not only moves into and out of the body but also moves in careful balance among the three fluid compartments. It is found in most body secretions, for example, saliva, gastric and intestinal secretions, bile, and pancreatic fluid. Therefore, continuous or excessive excretion of any of these fluids can result in a sodium deficit. Because of its role in regulating water balance, sodium imbalances usually are accompanied by water imbalances.

Hyponatremia is a sodium deficit, or serum sodium level of less than 135 mEq/L, and is, in acute care settings, a common electrolyte imbalance. Because of sodium's role in determining the osmolality of ECF, hyponatremia typically results in a low serum osmolality. Water is drawn out of the vascular compartment into interstitial tissues and the cells (Figure 51.10*A* ■), causing the clinical manifestations associated with this disorder. As sodium levels decrease, the brain and nervous system are affected by cellular edema. Severe hyponatremia, serum levels below 115 mEq/L, is a medical emergency and can cause permanent neurologic dysfunction (Walker, 2016).

Figure 51.10 ■ The extracellular sodium level affects cell size. *A*, In hyponatremia, cells swell; *B*, in hypernatremia, cells shrink in size.

Hypernatremia is excess sodium in ECF, or a serum sodium of greater than 145 mEq/L. Because the osmotic pressure of extracellular fluid is increased, fluid moves out of the cells into the ECF (Figure 51.10*B*). As a result, the cells become dehydrated. Like hyponatremia, the primary manifestations of hypernatremia are neurologic in nature.

It is important to note that normally an individual's thirst mechanism protects against hypernatremia. When an individual becomes thirsty, the body is stimulated to drink water, which helps correct the hypernatremia. Clients at highest risk for hypernatremia are those who are unable to access water, such as clients who are unconscious, clients who are unable to request fluids such as infants or older adults with dementia, or ill clients with an impaired thirst mechanism. Table 51.7 lists risk factors and clinical signs for hyponatremia and hypernatremia.

Potassium

Although the amount of potassium (K^+) in extracellular fluid is small, it is vital to normal neuromuscular and cardiac function. Normal renal function is important for maintenance of potassium balance, because 80% of potassium is excreted by the kidneys. Potassium must be replaced daily to maintain its balance, which normally happens through food intake.

Hypokalemia is a potassium deficit, defined as a serum potassium level of less than 3.5 mEq/L. Gastrointestinal losses of potassium through vomiting and gastric suction

TABLE 51.7 Electrolyte Imbalances

Risk Factors	Clinical Manifestations	Nursing Interventions
HYPONATREMIA Loss of Sodium • Gastrointestinal fluid loss • Sweating • Use of diuretics Gain of Water • Hypotonic tube feedings • Excessive drinking of water • Excess IV D_5W (dextrose in water) administration Syndrome of Inappropriate ADH (SIADH) • Head injury • AIDS • Malignant tumors	Lethargy, confusion, apprehension Muscle twitching Abdominal cramps Anorexia, nausea, vomiting Headache Seizures, coma *Laboratory findings*: Serum sodium $<$ 135 mEq/L Serum osmolality $<$ 280 mOsm/kg	Assess clinical manifestations. Monitor fluid intake and output. Monitor laboratory data (e.g., serum sodium). Assess client closely if administering hypertonic saline solutions. Encourage food and fluid high in sodium if permitted (e.g., table salt, bacon, ham, processed cheese). Limit water intake as indicated.
HYPERNATREMIA Loss of Water • Insensible water loss (hyperventilation or fever) • Diarrhea • Water deprivation Gain of Sodium • Parenteral administration of saline solutions • Hypertonic tube feedings without adequate water • Excessive use of table salt (1 tsp contains 2300 mg of sodium) Conditions such as: • Diabetes insipidus • Heat stroke	Thirst Dry, sticky mucous membranes Tongue red, dry, swollen Weakness Severe hypernatremia: • Fatigue, restlessness • Decreasing level of consciousness • Disorientation • Convulsions *Laboratory findings*: Serum sodium $>$ 145 mEq/L Serum osmolality $>$ 300 mOsm/kg	Monitor fluid intake and output. Monitor behavior changes (e.g., restlessness, disorientation). Monitor laboratory findings (e.g., serum sodium). Encourage fluids as ordered. Monitor diet as ordered (e.g., restrict intake of salt and foods high in sodium).
HYPOKALEMIA Loss of Potassium • Vomiting and gastric suction • Diarrhea • Heavy perspiration • Use of potassium-wasting drugs (e.g., diuretics) • Poor intake of potassium (as with debilitated clients, alcoholics, anorexia nervosa) • Hyperaldosteronism	Muscle weakness, leg cramps Fatigue, lethargy Anorexia, nausea, vomiting Decreased bowel motility Cardiac dysrhythmias Depressed deep-tendon reflexes Weak, irregular pulses *Laboratory findings*: Serum potassium $<$ 3.5 mEq/L Arterial blood gases (ABGs) may show alkalosis T-wave flattening and ST-segment depression on ECG	Monitor heart rate and rhythm. Monitor clients receiving digitalis (e.g., digoxin) closely, because hypokalemia increases risk of digitalis toxicity. Administer oral potassium as ordered with food or fluid to prevent gastric irritation. Administer IV potassium solutions at a rate no faster than 10–20 mEq/h; never administer undiluted potassium intravenously. For clients receiving IV potassium, monitor for pain and inflammation at the injection site. Teach clients about potassium-rich foods. Teach clients how to prevent excessive loss of potassium (e.g., through abuse of diuretics and laxatives).
HYPERKALEMIA Decreased Potassium Excretion • Renal failure • Hypoaldosteronism • Potassium-conserving diuretics High Potassium Intake • Excessive use of K^+-containing salt substitutes • Excessive or rapid IV infusion of potassium • Potassium shift out of the tissue cells into the plasma (e.g., infections, burns, acidosis)	Increased bowel mobility Irritability, apathy, confusion Cardiac dysrhythmias or arrest Muscle weakness, areflexia (absence of reflexes) Decreased heart rate Irregular pulse Paresthesias and numbness in extremities *Laboratory findings*: Serum potassium $>$ 5.0 mEq/L Peaked T wave, widened QRS on ECG	Closely monitor cardiac status and ECG. Administer diuretics and other medications such as glucose and insulin as ordered. Hold potassium supplements and K^+-conserving diuretics. Monitor serum K^+ levels carefully; a rapid drop may occur as potassium shifts into the cells. Teach clients to avoid foods high in potassium and salt substitutes.

TABLE 51.7 Electrolyte Imbalances—*continued*

Risk Factors	Clinical Manifestations	Nursing Interventions
HYPOCALCEMIA Surgical Removal of the Parathyroid Glands Conditions such as: • Hypoparathyroidism • Acute pancreatitis • Hyperphosphatemia • Thyroid carcinoma Inadequate Vitamin D Intake • Malabsorption • Hypomagnesemia • Alkalosis • Sepsis • Alcohol abuse	Numbness, tingling of the extremities and around the mouth Muscle tremors, cramps; if severe can progress to tetany and convulsions Cardiac dysrhythmias; decreased cardiac output Positive Trousseau's and Chvostek's signs (see Table 51.9 and Figure 51.11) Confusion, anxiety, possible psychoses Hyperactive deep-tendon reflexes *Laboratory findings*: Serum calcium $<$ 8.5 mg/dL (total) or 4.5 mEq/L (ionized) Lengthened QT intervals Prolonged ST segments	Closely monitor respiratory and cardiovascular status. Take precautions to protect a confused client. Administer oral or parenteral calcium supplements as ordered. When administering intravenously, closely monitor cardiac status and ECG during infusion. Teach clients at high risk for osteoporosis about: • Dietary sources rich in calcium. • Recommendation for 1000–1500 mg of calcium per day. • Calcium supplements. • Regular exercise. • Estrogen replacement therapy for postmenopausal women.
HYPERCALCEMIA • Prolonged immobilization Conditions such as • Hyperparathyroidism • Malignancy of the bone • Paget's disease	Lethargy, weakness Depressed deep-tendon reflexes Bone pain Anorexia, nausea, vomiting Constipation Polyuria, hypercalciuria Flank pain secondary to urinary calculi Dysrhythmias, possible heart block *Laboratory findings*: Serum calcium $>$ 10.5 mg/dL (total) or 5.5 mEq/L (ionized) Shortened QT intervals Shortened ST segments	Increase client movement and exercise. Encourage oral fluids as permitted to maintain a dilute urine. Teach clients to limit intake of food and fluid high in calcium. Encourage ingestion of fiber to prevent constipation. Protect a confused client; monitor for pathologic fractures in clients with long-term hypercalcemia. Encourage intake of acid–ash fluids (e.g., prune or cranberry juice) to counteract deposits of calcium salts in the urine.
HYPOMAGNESEMIA • Excessive loss from the gastrointestinal tract (e.g., from nasogastric suction, diarrhea, fistula drainage) • Long-term use of certain drugs (e.g., diuretics, aminoglycoside antibiotics) Conditions such as: • Chronic alcoholism • Pancreatitis • Burns	Neuromuscular irritability with tremors Increased reflexes, tremors, convulsions Positive Chvostek's and Trousseau's signs (see Table 51.9 and Figure 51.11) Tachycardia, elevated blood pressure, dysrhythmias Disorientation and confusion Vertigo Anorexia, dysphagia Respiratory difficulties *Laboratory findings*: Serum magnesium $<$ 1.5 mEq/L Prolonged PR intervals, widened QRS complexes, prolonged QT intervals, depressed ST segments, broad flattened T waves, prominent U waves	Assess clients receiving digitalis for digitalis toxicity. Hypomagnesemia increases the risk of toxicity. Take protective measures when there is a possibility of seizures: • Assess the client's ability to swallow water prior to initiating oral feeding. • Initiate safety measures to prevent injury during seizure activity. • Carefully administer magnesium salts as ordered. Encourage clients to eat magnesium-rich foods if permitted (e.g., whole grains, meat, seafood, and green leafy vegetables). Refer clients to alcohol treatment programs as indicated.
HYPERMAGNESEMIA Abnormal retention of magnesium, as in: • Renal failure • Adrenal insufficiency • Treatment with magnesium salts	Peripheral vasodilation, flushing Nausea, vomiting Muscle weakness, paralysis Hypotension, bradycardia Depressed deep-tendon reflexes Lethargy, drowsiness Respiratory depression, coma Respiratory and cardiac arrest if hypermagnesemia is severe *Laboratory findings*: Serum magnesium $>$ 2.5 mEq/L Electrocardiogram showing prolonged QT interval, prolonged PR interval, widened QRS complexes, tall T waves	Monitor vital signs and level of consciousness when clients are at risk. If patellar reflexes are absent, notify the primary care provider. Advise clients who have renal disease to contact their primary care provider before taking over-the-counter drugs.

DRUG CAPSULE

Diuretic Agent: furosemide (Lasix)

THE CLIENT WITH FLUID VOLUME EXCESS

Furosemide, which is a loop diuretic, inhibits sodium and chloride reabsorption in the loop of Henle and the distal renal tubule. This results in significant diuresis, with renal excretion of water, sodium chloride, potassium, magnesium, hydrogen, and calcium.

Furosemide is commonly used for the clinical management of edema secondary to heart failure, treatment of hypertension, and treatment of hepatic or renal disease. Therapeutic effects include diuresis and lowering of blood pressure.

NURSING RESPONSIBILITIES

- Assess the client's fluid status regularly. Assessment should include daily weight, close monitoring of intake and output, vital signs, skin turgor, edema, lung sounds, and mucous membranes.
- Monitor the client's potassium levels. Furosemide is a loop diuretic, which excretes potassium and may result in hypokalemia.
- Administer in the morning to avoid increased urination during hours of sleep.
- If the client is also taking digitalis glycosides, he or she should be assessed for anorexia, nausea, vomiting, muscle cramps, paresthesia, and confusion. The potassium-depleting effect of furosemide places the client at increased risk for digitalis toxicity.

CLIENT AND FAMILY TEACHING

- Medication should be taken exactly as directed. If a dose is missed, take it as soon as possible; however, if a day has been missed, do not double the dose the next day.
- Weigh yourself daily, and report weight gain or loss of more than 3 pounds in 1 day to your primary care provider.
- Contact your primary care provider immediately if you begin to experience muscle weakness, cramps, nausea, dizziness, numbness, or tingling of the extremities.
- Some form of potassium supplementation may be needed. Your primary care provider may order oral potassium supplements for you; if not, you may need to consume a diet high in potassium.
- Make position changes from lying to sitting and sitting to standing slowly in order to minimize dizziness.

Note: Prior to administering any medication, review all aspects in a current drug handbook or other reliable source.

are common causes of hypokalemia, as is the use of potassium-wasting diuretics, such as thiazide or loop diuretics. Symptoms of hypokalemia are usually mild until the level drops below 3 mEq/L, unless the decrease in potassium is rapid. When the decrease is gradual, the body compensates by shifting potassium from the intracellular environment into the serum.

Hyperkalemia is a potassium excess, defined as a serum potassium level greater than 5.0 mEq/L. Hyperkalemia is less common than hypokalemia, and rarely occurs in clients with normal renal function. It is, however, more dangerous than hypokalemia and can lead to cardiac arrest. As with hypokalemia, symptoms are more severe and occur at lower levels when the increase in potassium is rapid. Table 51.7 lists risk factors and clinical signs for hypokalemia and hyperkalemia.

Clinical Alert!

Potassium may be given intravenously for severe hypokalemia. It must **always** be diluted appropriately and **never** be given IV push. Potassium that is to be given IV should be mixed in the pharmacy and double-checked prior to administration by two nurses. The usual concentration of IV potassium is 20 to 40 mEq/L.

Calcium

Regulating the level of calcium (Ca^{2+}) in the body is more complex than the other major electrolytes, so calcium balance can be affected by many factors. Imbalances of this electrolyte are relatively common.

Hypocalcemia is a calcium deficit, defined as a total serum calcium level of less than 8.5 mg/dL or an ionized calcium level of less than 4.5 mEq/L. Severe depletion of calcium can cause tetany with muscle spasms and paresthesias (numbness and tingling around the mouth, hands, and feet), and can lead to seizures. Two signs indicate hypocalcemia: Chvostek's sign is a contraction of the facial muscles in response to tapping the facial nerve in front of the ear (Figure 51.11*A* ■); Trousseau's sign is a carpal spasm in response to inflating a blood pressure cuff on the upper arm to 20 mmHg greater than the systolic pressure for 2 to 5 minutes (Figure 51.11*B*). Clients at greatest risk for hypocalcemia are those whose parathyroid glands have been removed. This is frequently associated with thyroidectomy or other neck surgery, which can result in unintentional removal or damage to the parathyroid glands. Low serum magnesium levels (hypomagnesemia) and chronic alcoholism also increase the risk of hypocalcemia.

Hypercalcemia is a calcium excess, defined as a total serum calcium level greater than 10.5 mg/dL, or an ionized calcium level of greater than 5.5 mEq/L. It most often occurs when calcium is released in excess from the bony skeleton. This is usually due to malignancy or prolonged immobilization. The risk factors and clinical manifestations related to calcium imbalances are found in Table 51.7.

Magnesium

Magnesium (Mg^{2+}) imbalances are relatively common in hospitalized clients, although they may be unrecognized.

Hypomagnesemia is a magnesium deficiency, defined as a serum magnesium level of less than 1.5 mEq/L. It occurs more frequently than hypermagnesemia. Chronic alcoholism is the most common cause of hypomagnesemia. Magnesium deficiency also may aggravate the manifestations of alcohol withdrawal, such as delirium tremens (DTs).

A Chvostek sign **B** Trousseau sign

Figure 51.11 *A*, Positive Chvostek sign; *B*, positive Trousseau sign.
GERENE BAULDOFF; KAREN BURKE; PAULA GUBRUD, MEDICAL-SURGICAL NURSING, 7th Ed., © 2020. Reprinted and Electronically reproduced by permission of Pearson Education, Inc., New York, NY.

Hypermagnesemia is a magnesium excess, defined as a serum magnesium level above 2.5 mEq/L, due to increased intake or decreased excretion. It is often iatrogenic, meaning caused by medical treatment; usually the cause is oversupplementation with magnesium. Table 51.7 lists risk factors and manifestations for clients with altered magnesium balance.

Chloride

Because of the relationship between sodium ions and chloride ions (Cl^-), imbalances of chloride commonly occur in conjunction with sodium imbalances.

Hypochloremia is a chloride deficit, defined as a serum chloride level below 95 mEq/L, and is usually related to excess loss of chloride through the GI tract, kidneys, or sweating. Hypochloremic clients are at risk for alkalosis, and may experience muscle twitching, tremors, or tetany.

Hyperchloremia is a chloride excess, defined as a serum chloride level above 108 mEq/L. Excess replacement of sodium chloride or potassium chloride is a risk factor for high serum chloride levels, as are conditions that lead to hypernatremia. The manifestations of hyperchloremia include acidosis, weakness, and lethargy, with the risk of dysrhythmias or coma.

Phosphate

Phosphate (PO_4^{3-}) is found in both intracellular and extracellular fluid. Most of the phosphorus (P^+) in the body exists as PO_4^{3-}. Phosphate imbalances frequently are related to therapeutic interventions for other disorders.

Hypophosphatemia is a phosphate deficit, defined as a serum phosphate level of less than 2.5 mg/dL. Glucose and insulin administration and total parenteral nutrition can cause phosphate to shift into the cells from extracellular fluid compartments, leading to hypophosphatemia. Alcohol withdrawal, acid–base imbalances, and the use of antacids that bind with phosphate in the GI tract are other possible causes. Manifestations of hypophosphatemia include paresthesias, muscle weakness and pain, mental changes, and possibly seizures.

Hyperphosphatemia is a phosphate excess, defined as a serum phosphate level greater than 4.5 mg/dL. It occurs when phosphate shifts out of the cells into extracellular fluids (e.g., due to tissue trauma or chemotherapy), in renal failure, or when excess phosphate is administered or ingested. Infants who are fed cow's milk are at risk for hyperphosphatemia, as are individuals who use phosphate-containing enemas or laxatives. Manifestations of hyperphosphatemia include numbness and tingling around the mouth and in the fingertips, muscle spasms, and tetany.

Acid–Base Imbalances

Acid–base imbalances are usually classified as respiratory or metabolic by the cause of the disorder. Carbonic acid levels are normally regulated by the lungs through the retention or excretion of carbon dioxide, and problems lead to respiratory acidosis or alkalosis. Bicarbonate and hydrogen ion levels are regulated by the kidneys, and problems lead to metabolic acidosis or alkalosis. Healthy regulatory systems will attempt to correct acid–base imbalances, a process called **compensation**.

Respiratory Acidosis

Any condition that causes carbon dioxide retention, either due to hypoventilation or impaired lung function, causes carbonic acid levels to increase and pH to fall below 7.35, a condition known as **respiratory acidosis**. Serious lung diseases such as asthma and chronic obstructive pulmonary disease (COPD) are common causes of respiratory acidosis. Central nervous system depression due to anesthesia or a narcotic overdose can slow the respiratory rate enough to cause carbon dioxide retention. When respiratory acidosis occurs, the kidneys retain bicarbonate to restore the normal carbonic acid to bicarbonate ratio. The kidneys are relatively slow to respond to changes in acid–base balance, however, so this compensatory response may require hours to days to restore normal pH.

Respiratory Alkalosis

When an individual hyperventilates, more carbon dioxide than normal is exhaled, carbonic acid levels fall, and the pH rises to greater than 7.45. This condition is called **respiratory alkalosis**. Psychogenic or anxiety-related hyperventilation is a common cause of respiratory alkalosis. Other causes include fever and respiratory infections. In respiratory alkalosis, the kidneys will excrete bicarbonate to return pH to within the normal range. Often, however, the cause of the hyperventilation is eliminated and pH returns to normal before renal compensation occurs.

Metabolic Acidosis

When bicarbonate levels are low in relation to the amount of carbonic acid in the body, pH falls and **metabolic acidosis** develops. This may occur because of renal failure and the inability of the kidneys to excrete hydrogen ions and produce bicarbonate. It also may occur when too much acid is produced in the body, for example, in diabetic ketoacidosis or starvation when fat tissue is broken down for energy. Metabolic acidosis stimulates the respiratory center, and the rate and depth of respirations increase. Carbon dioxide is eliminated and carbonic acid levels fall, minimizing the change in pH. This respiratory compensation occurs within minutes of the onset of the pH imbalance.

Metabolic Alkalosis

In **metabolic alkalosis**, the amount of bicarbonate in the body exceeds the normal 20-to-1 ratio. Ingestion of bicarbonate of soda as an antacid is one cause of metabolic alkalosis, as is prolonged vomiting with loss of hydrochloric acid from the stomach. The respiratory center is depressed in metabolic alkalosis, and respirations slow and become shallower. Carbon dioxide is retained and carbonic acid levels increase, helping balance the excess bicarbonate. The risk factors and manifestations for acid–base imbalances are listed in Table 51.8.

●○● NURSING MANAGEMENT

Assessing

Assessing clients for fluid, electrolyte, and acid–base balance and imbalances is an important nursing responsibility. Components of the assessment include (a) the nursing

ANATOMY & PHYSIOLOGY REVIEW

Gas Exchange

Gas exchange. Oxygen from the alveoli moves into the blood, binds to red blood cells, and is carried to the body. Carbon dioxide dissolved in the blood or carried by red blood cells moves into the alveoli and is exhaled by the lungs.

SUSAN M. TURLEY MA, BSN, RN, ART, CMT, MEDICAL TERMINOLOGY, 4th Ed., © 2017. Reprinted and Electronically reproduced by permission of Pearson Education, Inc., New York, NY.

QUESTIONS

1. Hypoventilation can affect gas exchange. What are some causes of hypoventilation?
2. How does shallow breathing and hypoventilation cause $PaCO_2$ to increase and pH to decrease?
3. ABGs that indicate an increased $PaCO_2$ and a decreased pH reflect which acid–base imbalance?
4. Hyperventilation can also affect gas exchange. What are some causes of hyperventilation?
5. How does hyperventilation cause a decreased $PaCO_2$ and increased pH?
6. ABGs that indicate a decreased $PaCO_2$ and an increased pH reflect which acid–base imbalance?

Answers to Anatomy & Physiology Review Questions are available on the faculty resources site. Please consult with your instructor.

TABLE 51.8 Acid–Base Imbalances

Risk Factors	Clinical Manifestations	Nursing Interventions
RESPIRATORY ACIDOSIS Acute lung conditions that impair alveolar gas exchange (e.g., pneumonia, acute pulmonary edema, aspiration of foreign body, near-drowning) Chronic lung disease (e.g., asthma, cystic fibrosis, or emphysema) Overdose of narcotics or sedatives that depress respiratory rate and depth Brain injury that affects the respiratory center Airway obstruction	Increased pulse and respiratory rates Headache, dizziness Confusion, decreased level of consciousness (LOC) Convulsions Warm, flushed skin Chronic: Weakness Headache *Laboratory findings*: Arterial blood pH < 7.35 $PaCO_2 > 45$ mmHg HCO_3^- normal or slightly elevated in acute; >26 mEq/L in chronic	Frequently assess respiratory status and lung sounds. Monitor airway and ventilation; insert artificial airway and prepare for mechanical ventilation as necessary. Administer pulmonary therapy measures such as inhalation therapy, percussion and postural drainage, bronchodilators, and antibiotics as ordered. Monitor fluid intake and output, vital signs, and arterial blood gases. Administer narcotic antagonists as indicated. Maintain adequate hydration (2–3 L of fluid per day).
RESPIRATORY ALKALOSIS Hyperventilation due to: • Extreme anxiety • Elevated body temperature • Overventilation with a mechanical ventilator • Hypoxia • Salicylate overdose Brainstem injury Fever Increased basal metabolic rate	Complaints of shortness of breath, chest tightness Light-headedness with circumoral paresthesias and numbness and tingling of the extremities Difficulty concentrating Tremulousness, blurred vision *Laboratory findings (in uncompensated respiratory alkalosis)*: Arterial blood pH > 7.45 $PaCO_2 < 35$ mmHg	Monitor vital signs and ABGs. Assist client to breathe more slowly. Help client breathe in a paper bag or apply a rebreather mask (to inhale CO_2).
METABOLIC ACIDOSIS Conditions that increase nonvolatile acids in the blood (e.g., renal impairment, diabetes mellitus, starvation) Conditions that decrease bicarbonate (e.g., prolonged diarrhea) Excessive infusion of chloride-containing IV fluids (e.g., NaCl) Excessive ingestion of acids such as salicylates Cardiac arrest	Kussmaul's respirations (deep, rapid respirations) Lethargy, confusion Headache Weakness Nausea and vomiting *Laboratory findings*: Arterial blood pH < 7.35 Serum bicarbonate less than 22 mEq/L $PaCO_2 < 38$ mmHg with respiratory compensation	Monitor ABG values, intake and output, and LOC. Administer IV sodium bicarbonate carefully if ordered. Treat underlying problem as ordered.
METABOLIC ALKALOSIS Excessive acid losses due to: • Vomiting • Gastric suction Excessive use of potassium-losing diuretics Excessive adrenal corticoid hormones due to: • Cushing's syndrome • Hyperaldosteronism Excessive bicarbonate intake from: • Antacids • Parenteral $NaHCO_3$	Decreased respiratory rate and depth Dizziness Circumoral paresthesias, numbness and tingling of the extremities Hypertonic muscles, tetany *Laboratory findings*: Arterial blood pH > 7.45 Serum bicarbonate > 26 mEq/L $PaCO_2 > 45$ mmHg with respiratory compensation	Monitor intake and output closely. Monitor vital signs, especially respirations, and LOC. Administer ordered IV fluids carefully. Treat underlying problem.

history, (b) physical assessment of the client, (c) clinical measurements, and (d) review of laboratory test results.

Nursing History

The nursing history is particularly important for identifying clients who are at risk for fluid, electrolyte, and acid–base imbalances. A client's current and past medical history reveals conditions such as chronic lung disease or diabetes mellitus that can disrupt normal balances. Medications prescribed to treat acute or chronic conditions (e.g., diuretic therapy for hypertension) also may place a client at risk for altered homeostasis. Functional, developmental, and socioeconomic factors must also be considered in assessing a client's risk. Older adults and very young children, clients who must depend on others to meet their nutrition and hydration needs, and individuals who cannot afford or do not have the means to cook food for a balanced diet

(e.g., homeless individuals) are at greater risk for fluid and electrolyte imbalances. Common risk factors are listed in Box 51.2.

BOX 51.2 Common Risk Factors for Fluid, Electrolyte, and Acid–Base Imbalances

CHRONIC DISEASES AND CONDITIONS
- Chronic lung disease (COPD, asthma, cystic fibrosis)
- Heart failure
- Kidney disease
- Diabetes mellitus
- Cushing's syndrome or Addison's disease
- Cancer
- Malnutrition, anorexia nervosa, bulimia
- Ileostomy

ACUTE CONDITIONS
- Acute gastroenteritis
- Bowel obstruction
- Head injury or decreased level of consciousness
- Trauma such as burns or crushing injuries
- Surgery
- Fever, draining wounds, fistulas

MEDICATIONS
- Diuretics
- Corticosteroids
- Nonsteroidal anti-inflammatory drugs

TREATMENTS
- Chemotherapy
- IV therapy and total parenteral nutrition
- Nasogastric suction
- Enteral feedings
- Mechanical ventilation

OTHER FACTORS
- Age: Very old or very young
- Inability to access food and fluids independently

When obtaining a nursing history, the nurse needs to not only recognize risk factors but also gather data about the client's food and fluid intake, fluid output, and the presence of signs or symptoms suggestive of altered fluid and electrolyte balance. The Assessment Interview provides examples of questions to elicit information regarding fluid, electrolyte, and acid–base balance.

Physical Assessment

Physical assessment to evaluate a client's fluid, electrolyte, and acid–base status focuses on the skin, the oral cavity and mucous membranes, the eyes, the cardiovascular and respiratory systems, and neurologic and muscular status. Data from this physical assessment are used to expand and verify information obtained in the nursing history. Refer to Tables 51.5 through 51.9 for possible abnormal findings related to specific imbalances.

Clinical Measurements

Three simple clinical measurements that the nurse can initiate without a primary care provider's order are daily weights, vital signs, and fluid intake and output.

Daily Weights

Daily weights provide a relatively accurate assessment of a client's fluid status. Significant changes in weight over a short time, for example, more than 2.3 kg (5 lb) in a week or more than 1 kg (2.2 lb) in 24 hours, are indicative of acute fluid changes. Each kilogram (2.2 lb) of weight gained or lost corresponds to 1 L of fluid gained or lost. Such fluid gains or losses indicate changes in total body fluid volume rather than in any specific compartment, such as the intravascular compartment. Rapid losses or gains of 5% to 8% of total body weight indicate moderate to severe fluid volume deficits or excesses.

To obtain accurate weight measurements, the scale should be balanced before each use, and the client should be weighed (a) at the same time each day (e.g., before breakfast and after the first void), (b) wearing the same or similar clothing, and (c) on the same scale. The type of scale (i.e., standing, bed, or chair) should be documented.

Regular assessment of weight is particularly important for clients in the community and extended care facilities who are at risk for fluid imbalance. For these clients, measuring intake and output may be impractical because of lifestyle or problems with incontinence. Regular weight measurement, either daily, every other day, or weekly, provides valuable information about the client's fluid status.

Vital Signs

Changes in vital signs may indicate, or in some cases precede, fluid, electrolyte, and acid–base imbalances. For example, elevated body temperature may be a result of dehydration or a cause of increased body fluid losses.

Tachycardia is an early sign of hypovolemia. Pulse *volume* will decrease in FVD and increase in FVE. Irregular pulse rhythms may occur with electrolyte imbalances. Changes in respiratory rate and depth may cause respiratory acid–base imbalances or indicate a compensatory mechanism in metabolic acidosis or alkalosis.

Blood pressure (BP), a sensitive measure for detecting blood volume changes, may fall significantly with FVD and hypovolemia or increase with FVE. Postural, or orthostatic, hypotension may also occur with FVD and hypovolemia. To assess for orthostatic hypotension, measure the client's BP and pulse in a supine position. Allow the client to remain in that position for 3 to 5 minutes, leaving the blood pressure cuff on the arm. Ask the client to stand up and immediately reassess the BP and pulse. A drop of 10 to 15 mmHg in the systolic BP with a corresponding drop in diastolic pressure and an increased pulse rate (by 10 or more beats per minute) is indicative of orthostatic or postural hypotension.

Fluid Intake and Output

Measurement and recording of all fluid intake and output (I&O) during a 24-hour period provides important data

TABLE 51.9 Focused Physical Assessment for Fluid, Electrolyte, or Acid–Base Imbalances

System	Assessment Focus	Technique	Possible Abnormal Findings
Skin	Color, temperature, moisture Turgor Edema	Inspection, palpation Gently pinch up a fold of skin over sternum for adults, on the abdomen or medial thigh for children Inspect for visible swelling around eyes, in fingers, and in lower extremities Compress the skin over the dorsum of the foot, around the ankles, over the tibia, in the sacral area	Flushed, warm, very dry Moist or diaphoretic Cool and pale Poor turgor: Skin remains tented for several seconds instead of immediately returning to normal position Skin around eyes is puffy, lids appear swollen; rings are tight; shoes leave impressions on feet Depression remains (pitting): See scale for describing edema in Figure 51.9.
Mucous membranes	Color, moisture	Inspection	Mucous membranes dry, dull in appearance; tongue dry and cracked
Eyes	Firmness	Gently palpate eyeball with lid closed	Eyeball feels soft to palpation
Fontanels (infant)	Firmness, level	Inspect and gently palpate anterior fontanel	Fontanel bulging, firm Fontanel sunken, soft
Cardiovascular system	Heart rate Peripheral pulses Blood pressure Capillary refill Venous filling	Auscultation, cardiac monitor Palpation Auscultation of Korotkoff's sounds BP assessment lying and standing Palpation Inspection of jugular veins and hand veins	Tachycardia, bradycardia; irregular; dysrhythmias Weak and thready; bounding Hypotension Postural hypotension Slowed capillary refill Jugular venous distention; flat jugular veins, poor venous refill
Respiratory system	Respiratory rate and pattern Lung sounds	Inspection Auscultation	Increased or decreased rate and depth of respirations Crackles or moist rales
Neurologic	Level of consciousness (LOC) Orientation, cognition Motor function Reflexes Abnormal reflexes	Observation, stimulation Questioning Strength testing Deep-tendon reflex (DTR) testing *Chvostek's sign*: Tap over facial nerve about 2 cm anterior to tragus of ear *Trousseau's sign*: Inflate a blood pressure cuff on the upper arm to 20 mmHg greater than the systolic pressure, leave in place for 2–5 min	Decreased LOC, lethargy, stupor, or coma Disoriented, confused; difficulty concentrating Weakness, decreased motor strength Hyperactive or depressed DTRs Facial muscle twitching including eyelids and lips on side of stimulus Carpal spasm: contraction of hand and fingers on affected side

ASSESSMENT INTERVIEW Fluid, Electrolyte, and Acid–Base Balance

CURRENT AND PAST MEDICAL HISTORY

- Are you currently seeing a healthcare provider for treatment of any chronic diseases such as kidney disease, heart disease, lung disease, high blood pressure, diabetes mellitus, diabetes insipidus, or thyroid, parathyroid, or adrenal disorders?
- Have you recently experienced any acute conditions such as gastroenteritis, severe trauma, head injury, or surgery?

MEDICATIONS AND TREATMENTS

- Are you currently taking any medications on a regular basis such as diuretics, steroids, potassium supplements, calcium supplements, hormones, salt substitutes, or antacids?
- Have you recently undergone any treatments such as dialysis, parenteral nutrition, tube feedings, or been on a ventilator?

FOOD AND FLUID INTAKE

- How much and what type of fluids do you drink each day?
- Describe your diet for a typical day. (Pay particular attention to the client's intake of foods high in sodium, and of protein, whole grains, fruits, and vegetables.)
- Have there been any recent changes in your food or fluid intake, for example, as a result of following a weight-loss program?
- Are you on any type of restricted diet?
- Has your food or fluid intake recently been affected by changes in appetite, nausea, or other factors such as pain or difficulty breathing?

FLUID OUTPUT

- Have you noticed any recent changes in the frequency or amount of urine output?

Continued on page 1364

ASSESSMENT INTERVIEW Fluid, Electrolyte, and Acid–Base Balance—*continued*

- Have you recently experienced any problems with vomiting, diarrhea, or constipation?
- Have you noticed any other unusual fluid losses such as excessive sweating?

FLUID, ELECTROLYTE, AND ACID–BASE IMBALANCES

- Have you gained or lost weight in recent weeks?
- Have you recently experienced any symptoms such as excessive thirst, dry skin or mucous membranes, dark or concentrated urine, or low urine output?
- Do you have problems with swelling of your hands, feet, or ankles? Do you ever have difficulty breathing, especially when lying down or at night? How many pillows do you use to sleep?
- Have you recently experienced any of the following symptoms: difficulty concentrating or confusion; dizziness or feeling faint; muscle weakness, twitching, cramping, or spasm; excessive fatigue; abnormal sensations such as numbness, tingling, burning, or prickling; abdominal cramping or distention; heart palpitations?

about a client's fluid and electrolyte balance. Generally, I&O are measured for hospitalized clients, particularly those at increased risk for fluid and electrolyte imbalance.

The unit used to measure I&O is the milliliter (mL). In household measures, 30 mL is roughly equivalent to 1 fluid ounce, 500 mL to 1 pint, and 1000 mL to 1 quart. To measure fluid intake, nurses convert household measures such as a cup or soup bowl to metric units. Most agencies have a form for recording I&O, usually a bedside or computer record on which the nurse lists all items measured and the quantities per shift (Figure 51.12 ■).

Usually these forms provide conversion tables, since the sizes of dishes vary from agency to agency. Examples of equivalents are given in Box 51.3. Some agencies have a different form for recording the specifics of IV fluids, such as the type of solution, additives, time started, amount absorbed, and amount remaining per shift.

It is important to inform clients, family members, and all caregivers that accurate measurements of the client's fluid I&O are required, explaining why and emphasizing

BOX 51.3 Commonly Used Fluid Containers and Their Volumes

Water glass	200 mL
Juice glass	120 mL
Cup	180 mL
Soup bowl	
Adult	180 mL
Child	100 mL
Teapot	240 mL
Creamer	
Large	90 mL
Small	30 mL
Water pitcher	1000 mL
Jell-O, custard dish	100 mL
Ice cream dish	120 mL
Paper cup	
Large	200 mL
Small	120 mL

Figure 51.12 ■ A sample EHR 24-hour fluid intake and output record.

the need to use a bedpan, urinal, commode, or in-toilet collection device (unless a urinary drainage system is in place). Instruct the client not to put toilet tissue into the container with urine. Clients who wish to be involved in recording fluid intake measurements need to be taught how to compute the values and what foods are considered fluids.

To measure fluid intake, each item of fluid consumed or administered is recorded, specifying the time and type of fluid. All of the following fluids need to be recorded:

- ***Oral fluids:*** Water, milk, juice, soft drinks, coffee, tea, cream, soup, and any other beverages. Include water taken with medications. To measure the amount of water consumed from a water pitcher, measure how much water remains in the pitcher and subtract this amount from the volume of the full pitcher.
- ***Ice chips:*** Record the fluid volume as approximately one-half the volume of the ice chips. For example, if the ice chips fill a cup holding 200 mL and the client consumed all of the ice chips, the volume consumed would be recorded as 100 mL.
- ***Foods that are or become liquid at room temperature:*** These include ice cream, sherbet, custard, and gelatin. Do not measure foods that are pureed, because purees are simply solid foods prepared in a different form.
- ***Tube feedings:*** Remember to include the volume of water used for flushes before and after medication administration, intermittent feedings, residual checks, or any other water given via a feeding tube.
- ***Parenteral fluids:*** The exact amount of IV fluid administered must be recorded, since some fluid containers may be overfilled. Blood transfusions are included in the total.
- ***IV medications:*** IV medications that are administered as an intermittent or continuous infusion must also be included (e.g., ceftazidime 1 g in 50 mL of sterile water). Most IV medications are mixed in 50 to 100 mL of solution.
- ***Catheter or tube irrigants:*** Fluid used to irrigate urinary catheters, nasogastric tubes, and intestinal tubes must be recorded if not immediately withdrawn as part of the irrigation.

To measure fluid output, measure the following fluids (remember to observe appropriate infection control precautions):

- ***Urinary output:*** Following each voiding, pour the urine into a measuring container, note the amount, and record the amount and time on the I&O form. For clients with retention catheters, empty the drainage bag into a measuring container at the end of the shift (or at prescribed times if output is to be measured more often). Note and record the amount of urine output. In intensive care areas, urine output often is measured hourly. If a client is incontinent of urine, estimate and record these outputs. For example, for an incontinent client the nurse might record "Incontinent × 3" or "Drawsheet soaked in 12-in. diameter." A more accurate estimate of the urine output of infants and incontinent clients may be obtained by first weighing diapers or incontinence pads that are dry, and then subtracting this weight from the weight of the soiled items. Each gram of weight left after subtracting is equal to 1 mL of urine. If urine is frequently soiled with feces, the number of voidings may be recorded rather than the volume of urine.
- ***Vomitus and liquid feces:*** The amount and type of fluid and the time need to be specified.
- ***Tube drainage:*** This includes gastric or intestinal drainage.
- ***Wound and fistula drainage:*** Drainage may be recorded by documenting the type and number of dressings or linen saturated with drainage, or by measuring the exact amount of drainage collected in a vacuum drainage (e.g., Hemovac) or gravity drainage system.

Fluid I&O measurements are totaled at the end of the shift (every 8 to 12 hours), and the totals are recorded in a client's chart. In intensive care areas, nurses may record I&O hourly. Usually the staff on the night shift totals the amounts of I&O recorded for each shift and records the 24-hour total.

To determine whether fluid output is proportional to fluid intake, or whether there are any changes in a client's fluid status, (a) compare the total 24-hour fluid output measurement with the total 24-hour fluid intake measurement and (b) compare both to previous measurements. Urinary output is normally equivalent to the amount of fluid intake; the usual range is 1500 to 2000 mL in 24 hours, or 40 to 80 mL in 1 hour (0.5 mL/kg per hour). Clients whose output substantially exceeds intake are at risk for fluid volume deficit, whereas clients whose intake substantially exceeds output are at risk for fluid volume excess. In assessing a client's fluid balance it is important to consider additional factors that may affect I&O. For example, a client who is extremely diaphoretic or has rapid, deep respirations has fluid losses that cannot be measured but must still be considered in evaluating fluid status.

When there is a significant discrepancy between intake and output or when fluid intake or output is inadequate (for example, a urine output of less than 30 mL/h in an adult), this information should be reported to the primary care provider.

Laboratory Tests

Many laboratory studies are conducted to determine a client's fluid, electrolyte, and acid–base status. Some of the more common tests are discussed here.

Serum Electrolytes

Serum electrolyte levels are often ordered for clients admitted to the hospital as a screening test for electrolyte and acid–base imbalances. Serum electrolytes also are routinely assessed for clients at risk in the community, for example, clients who are being treated with a diuretic for hypertension or heart failure. The most commonly

ordered serum tests are for sodium, potassium, chloride, magnesium, and bicarbonate ions. Normal values of commonly measured electrolytes are shown in Box 51.4. Some primary care providers use a diagram format for keeping track of the client's electrolytes when documenting in their progress notes (Figure 51.13 ■).

BOX 51.4 Normal Electrolyte Values for Adults*

Venous Blood	
Sodium	135–145 mEq/L
Potassium	3.5–5.0 mEq/L
Chloride	95–108 mEq/L
Calcium, total	4.5–5.5 mEq/L or 8.5–10.5 mg/dL
Calcium, ionized	56% of total calcium (2.5 mEq/L or 4.0–5.0 mg/dL)
Magnesium	1.5–2.5 mEq/L or 1.6–2.5 mg/dL
Phosphate (phosphorus)	1.8–2.6 mEq/L or 2.5–4.5 mg/dL
Serum osmolality	280–300 mOsm/kg water

*Normal laboratory values vary from agency to agency.

Complete Blood Count

A complete blood count (CBC), another basic screening test, includes information about **hematocrit (Hct)**, which measures the percentage of the volume of whole blood that is composed of RBCs. Hematocrit is a measure of the volume of cells in relation to plasma and is, therefore, affected by changes in plasma volume; hematocrit increases with dehydration and decreases with overhydration. Normal hematocrit values are 40% to 54% in men and 37% to 47% in women.

Osmolality

Serum osmolality is a measure of the solute concentration of blood. The particles included are sodium ions, glucose, and urea (blood urea nitrogen, or BUN). Serum osmolality can be estimated by doubling the serum sodium value, because sodium and its associated chloride ions are the major determinants of serum osmolality. Serum osmolality is used primarily to evaluate fluid balance. Normal values are 280 to 300 mOsm/kg. An increase in serum osmolality indicates a fluid volume deficit; a decrease reflects a fluid volume excess.

Figure 51.13 ■ *A*, Format for a diagram of serum electrolyte results; *B*, example that may be seen in a primary care provider's documentation notes.

Urine osmolality is a measure of the solute concentration of urine. The particles included are nitrogenous wastes, such as creatinine, urea, and uric acid. Normal values are 500 to 800 mOsm/kg. An increased urine osmolality indicates a fluid volume deficit; a decreased urine osmolality reflects a fluid volume excess.

Urine Specific Gravity

Specific gravity is an indicator of urine concentration that correlates with urine osmolality, and it can be measured quickly and easily by nursing personnel. Normal specific gravity ranges from 1.005 to 1.030 (usually 1.010 to 1.025). When urine osmolality is high, in fluid volume deficit, the specific gravity rises; when urine osmolality is low, in fluid volume excess, the specific gravity is low.

Urine pH

Measurement of urine pH may be obtained by laboratory analysis or by using a dipstick on a freshly voided specimen. Because the kidneys play a critical role in regulating acid–base balance, assessment of urine pH can be useful in determining whether the kidneys are responding appropriately to acid–base imbalances. Normally the pH of the urine is relatively acidic, averaging about 6.0, but a range of 4.6 to 8.0 is considered normal. In metabolic acidosis, urine pH should decrease as the kidneys retain bicarbonate and excrete hydrogen ions; in metabolic alkalosis, the pH should increase as the kidneys retain hydrogen ions and excrete bicarbonate.

Arterial Blood Gases

Arterial blood gases (ABGs) are performed to evaluate a client's acid–base balance and oxygenation. Arterial blood is used because it provides a more accurate reflection of gas exchange in the pulmonary system than venous blood. Blood gases may be drawn by laboratory technicians, respiratory therapy personnel, or nurses with specialized skills. Because a high-pressure artery is used to obtain blood, it is important to apply pressure to the puncture site for at least 5 minutes after the procedure to reduce the risk of bleeding or bruising.

Six measurements are commonly used to interpret arterial blood gas tests:

- pH is a measure of the relative acidity or alkalinity of the blood, and is an inverse measure of the number of hydrogen ions in a solution. The normal range for arterial pH is narrow, and death may ensue with pH values below 6.8 or above 7.8.
- PaO_2 is the partial pressure of oxygen dissolved in arterial plasma, and is an indirect measure of blood oxygen content. PaO_2 represents one of the two forms in which oxygen is transported in blood, and accounts for only about 3% of the oxygen content of the blood.
- $PaCO_2$ is the partial pressure of carbon dioxide in arterial plasma, and is the respiratory component of acid–base determination. Because carbon dioxide is regulated by the lungs, $PaCO_2$ is used to determine if an acid–base imbalance is respiratory in origin.
- HCO_3^- is a measure of the bicarbonate dissolved in arterial plasma, and represents the metabolic component of acid–base balance.

- Base excess (BE) is a calculated value of bicarbonate levels, also reflective of the metabolic component of acid–base balance. If the number is preceded by a plus sign, it represents a base excess; a BE above +2 indicates alkalosis. If the number is preceded by a minus sign, it represents a base deficit; a BE below −2 indicates acidosis.
- SpO_2 is oxygen saturation, which represents the percentage of hemoglobin that is combined (saturated) with oxygen. SpO_2 is the other form in which oxygen is transported in the blood and accounts for about 97% of the oxygen in the blood.

Normal ABG values are listed in Table 51.10 along with changes associated with common acid–base imbalances. Note that although the PaO_2 and SpO_2 are important for assessing respiratory status, they generally do not provide useful information for assessing acid–base balance and so are not included in this table.

When evaluating ABG results to determine acid–base balance, it is important to use a systematic approach such as the one outlined in Box 51.5. Nurses need to assess each measurement individually, and then look at the interrelationships to determine what type of acid–base imbalance may be present.

TABLE 51.10 Arterial Blood Gas Values

NORMAL VALUES OF ARTERIAL BLOOD GASES*	
pH	7.35–7.45
PaO_2	80–100 mmHg
$PaCO_2$	35–45 mmHg
HCO_3^-	22–26 mEq/L
Base excess	−2 to +2 mEq/L
O_2 saturation	95–98%

ARTERIAL BLOOD GAS VALUES IN COMMON ACID–BASE DISORDERS

Disorder		ABG Values
Respiratory acidosis	pH	<7.35
	$PaCO_2$	>45 mmHg (excess CO_2 and carbonic acid)
	HCO_3^-	Normal (or >26 mEq/L with renal compensation)
Respiratory alkalosis	pH	>7.45
	$PaCO_2$	<35 mmHg (inadequate CO_2 and carbonic acid)
	HCO_3^-	Normal (or <22 mEq/L with renal compensation)
Metabolic acidosis	pH	<7.35
	$PaCO_2$	Normal (or <35 mmHg with respiratory compensation)
	HCO_3^-	<22 mEq/L (inadequate bicarbonate)
Metabolic alkalosis	pH	>7.45
	$PaCO_2$	Normal (or >45 mmHg with respiratory compensation)
	HCO_3^-	>26 mEq/L (excess bicarbonate)

*Some normal values will vary according to the kind of test carried out in the laboratory. Nurses are advised to use the normal values issued by the agency when interpreting laboratory results.

BOX 51.5 Interpreting ABGs—Do You Have a Match?

1. Look at each number separately.
   - Label the pH:
     - If the pH is less than 7.35, the problem is acidosis.
     - If the pH is greater than 7.45, the problem is alkalosis.
   - Label the $PaCO_2$:
     - If the $PaCO_2$ is less than 35 mmHg, more carbon dioxide is being exhaled than normal and indicates respiratory alkalosis or compensation for a metabolic imbalance.
     - If the $PaCO_2$ is greater than 45 mmHg, less carbon dioxide is being exhaled than normal and indicates respiratory acidosis or compensation for a metabolic imbalance.
   - Label the bicarbonate:
     - If the HCO_3^- is less than 22 mEq/L, bicarbonate levels are lower than normal, indicating metabolic acidosis or compensation for a respiratory imbalance.
     - If the HCO_3^- is greater than 26 mEq/L, bicarbonate levels are higher than normal, indicating metabolic alkalosis or compensation for a respiratory imbalance.
2. Determine the cause of the acid–base imbalance.
   - Look at the pH—is it acidosis, alkalosis, or within the normal range?
3. Determine if the origin of the imbalance is respiratory or metabolic.
   - Check the $PaCO_2$ and HCO_3^-. Which one corresponds with the same acid–base status as the pH?

     EXAMPLE

     pH = 7.33 (acidosis)

     $PaCO_2$ = 55 (acidosis)

     HCO_3 = 29 (alkalosis)

     $PaCO_2$ (acidosis) MATCHES the pH (acidosis) = respiratory problem

     Client has respiratory acidosis.
4. Look for evidence of compensation.
   - Look at the value that does **not** match the pH:

     EXAMPLES

     a. In respiratory acidosis (pH < 7.35, $PaCO_2$ > 45 mmHg), if the HCO_3^- is greater than 26 mEq/L, the kidneys are retaining bicarbonate to minimize the acidosis: renal compensation.

     b. In respiratory alkalosis (pH > 7.45, $PaCO_2$ < 35 mmHg), if the HCO_3^- is less than 22 mEq/L, the kidneys are excreting bicarbonate to minimize the alkalosis: renal compensation.

     c. In metabolic acidosis (pH < 7.35, HCO_3^- < 22 mEq/L), if the $PaCO_2$ is less than 35 mmHg, carbon dioxide is being eliminated to minimize the acidosis: respiratory compensation.

     d. In metabolic alkalosis (pH > 7.45, HCO_3^- > 26 mEq/L), if the $PaCO_2$ is greater than 45 mmHg, carbon dioxide is being retained to compensate for excess base: respiratory compensation.

Note: If the pH is within normal range, the body has completely compensated. Complete metabolic compensation takes time to develop and is the result of a chronic condition (e.g., chronic respiratory acidosis with COPD). If the pH is not within the normal range, compensation is partial.

Diagnosing

Examples of diagnoses for clients with fluid and acid–base imbalances can include actual or potential for: decreased fluid volume, increased fluid volume, and altered gas exchange. Clinical applications of selected diagnoses are shown in the Nursing Care Plan and the Concept Map at the end of this chapter.

Fluid, electrolyte, and acid–base imbalances affect many other body areas and as a consequence may be the etiology of other nursing diagnoses, such as dry mucous membranes related to fluid volume deficit; skin breakdown related to dehydration or edema; inadequate cardiac output related to hypovolemia or cardiac dysrhythmias secondary to electrolyte imbalance (K^+ or Mg^{2+}); risk for injury (e.g., dizziness, orthostatic hypotension) related to hypovolemia; confusion related to electrolyte imbalance.

Planning

When planning care a nurse identifies nursing interventions that will assist the client to achieve these broad goals:

- Maintain or restore normal fluid balance.
- Maintain or restore normal balance of electrolytes in the intracellular and extracellular compartments.
- Maintain or restore gas exchange and oxygenation.
- Prevent associated risks (e.g., tissue breakdown, decreased cardiac output, confusion, other neurologic signs).

Goals will vary according to the diagnosis and defining characteristics for each client. Appropriate preventive and corrective nursing interventions that relate to these must be identified. Specific nursing activities can be selected to meet a client's individual needs. Examples of application of these using NIC and NOC designations are shown in the Nursing Care Plan and the Concept Map at the end of this chapter. Examples of NIC interventions related to fluid, electrolyte, and acid–base balance include the following:

- Acid–base management
- Electrolyte management
- Fluid monitoring
- Hypovolemia management
- Intravenous (IV) therapy.

Specific nursing activities associated with each of these interventions can be selected to meet the individual needs of the client.

Nursing activities to meet goals and outcomes related to fluid, electrolyte, and acid–base imbalances are discussed in the next section. These include (a) monitoring fluid intake and output, cardiovascular and respiratory status, and results of laboratory tests; (b) assessing the client's weight, location and extent of edema if present, skin turgor and skin status, specific gravity of urine, and level of consciousness and mental status; (c) fluid intake modifications; (d) dietary changes; (e) parenteral fluid, electrolyte, and blood replacement; and (f) other appropriate measures such as administering prescribed medications and oxygen, providing skin care and oral hygiene, positioning the client appropriately, and scheduling rest periods.

Planning for Home Care

To provide for continuity of care, a client's needs for assistance with care in the home need to be considered. Home care planning includes assessment of a client's and family's resources and abilities for care, and the need for referrals and home health services.

QSEN Patient-Centered Care: Assessing Fluid, Electrolyte, and Acid–Base Balance

To establish a home care plan, the nurse needs to assess specific data such as the following:

CLIENT

- ***Risk factors for imbalances:*** the client's age, medications such as diuretic therapy or corticosteroids, and presence of chronic diseases such as diabetes mellitus, heart disease, lung disease, or dementia (see Box 51.2 on page 1362)
- ***Self-care abilities for maintaining food and fluid intake:*** mobility; ability to chew and swallow; ability to access fluids and respond to thirst, to purchase food, and prepare a balanced diet
- ***Current level of knowledge (as appropriate):*** prescribed diet, any fluid restrictions, activity restrictions, actions and side effects of prescribed medications, regular weight monitoring, gastric tube care and enteral feedings, central line or PICC catheter care, and parenteral fluids and nutrition

FAMILY

- ***Caregiver availability, skills, and responses:*** availability and willingness to assume responsibility for care, knowledge and ability to provide assistance with preparing food and maintaining adequate intake of food and fluids, knowledge of risk factors and early warning signs of problems
- ***Family role changes and coping:*** effect on financial status, parenting and spousal roles, social roles
- ***Alternate potential primary or respite caregivers:*** other family members, friends, volunteers, church members, paid caregivers or housekeeping services; available community respite care (e.g., adult day care, senior centers)

COMMUNITY

- ***Current knowledge of and experience with community resources:*** home health agencies, organizations that offer financial assistance or assistance with food preparation, Meals on Wheels or meal services (e.g., at senior centers, homeless shelters), pharmacies, home IV services, and respiratory care services

Based on the data gathered in assessment of the home situation, the nurse tailors the teaching plan for the client and family (see Client Teaching).

CLIENT TEACHING Promoting Fluid and Electrolyte Balance

- Consume six to eight glasses of water daily.
- Avoid excess amounts of foods or fluids high in salt, sugar, and caffeine.
- Eat a well-balanced diet. Include adequate amounts of milk, milk products, or calcium-enriched alternatives to maintain bone calcium levels.
- Limit alcohol intake because it has a diuretic effect.
- Increase fluid intake before, during, and after strenuous exercise, particularly when the environmental temperature is high, and replace lost electrolytes from excessive perspiration as needed with commercial electrolyte solutions.
- Maintain normal body weight and body mass index for age and gender.
- Learn about and monitor side effects of medications that affect fluid and electrolyte balance (e.g., diuretics) and ways to handle side effects.
- Recognize possible risk factors for fluid and electrolyte imbalance such as prolonged or repeated vomiting, frequent watery stools, or inability to consume fluids because of illness.
- Seek prompt professional healthcare for notable signs of fluid imbalance such as sudden weight gain or loss, decreased urine volume, swollen ankles, shortness of breath, dizziness, or confusion.

CLIENT TEACHING Home Care and Fluid, Electrolyte, and Acid–Base Balance

MONITORING FLUID INTAKE AND OUTPUT

- Teach and provide the rationale for monitoring fluid intake and output to the client and family as appropriate, for example, how to use a commode or collection device ("hat") in the toilet, how to empty and measure urinary catheter drainage, or how to count or weigh diapers.
- Instruct and provide the rationale for regular weight monitoring to the client and family, including weighing at the same time every day, using the same scale, and with the client wearing the same amount of clothing.
- Educate and provide the rationale to the client and family on when to contact a healthcare professional, such as in the cases of a significant change in urine output; any change of 2.2 kilograms (5 pounds) or more in a 1- to 2-week period or 1 kilogram (2 pounds) or more in 24 hours; prolonged episodes of vomiting, diarrhea, or inability to eat or drink; dry, sticky mucous membranes; extreme thirst; swollen fingers, feet, ankles, or legs; difficulty breathing, shortness of breath, need for an increased number of pillows to sleep on, or rapid heartbeat; and changes in behavior or mental status.

MAINTAINING FOOD AND FLUID INTAKE

- Instruct the client and family about any diet or fluid restrictions, such as a low-sodium diet.
- Teach family members the rationale for the importance of offering fluids regularly to clients who are unable to meet their own needs because of age, impaired mobility or cognition, or other conditions such as impaired swallowing due to a stroke.
- If the client is on enteral or IV fluids and feeding at home, teach and provide rationales to caregivers about proper administration and care. Contact a home health or home IV service to provide services and teaching.

SAFETY

- Instruct and provide the rationale to the client for changing positions slowly if appropriate, especially when moving from a supine to a sitting or standing position.
- Inform and provide the rationale to the client and family about the importance of good mouth and skin care. Teach the client to change positions frequently and to elevate the feet when sitting for a long period.
- Teach the client and family how to care for IV access sites or gastric tubes. Include what to do if tubes become dislodged.

MEDICATIONS

- Emphasize the importance of and rationale for taking medications as prescribed.
- Instruct clients taking diuretics to take the medication in the morning. If a second daily dose is prescribed, they should take it in the late afternoon to avoid disrupting sleep to urinate.
- Inform clients about any expected side effects of prescribed medications and how to handle them (e.g., if a potassium-depleting diuretic is prescribed, increase intake of potassium-rich foods; if taking a potassium-sparing diuretic, avoid excess potassium intake such as using a salt substitute).
- Teach clients when to contact their primary care provider, for example, if they are unable to take a prescribed medication or have signs of an allergic or toxic reaction to a medication.

MEASURES SPECIFIC TO CLIENT'S PROBLEM

- Provide instructions and rationales specific to the client's fluid, electrolyte, or acid–base imbalance, such as:
  a. Fluid volume deficit
  b. Risk for fluid volume deficit
  c. Fluid volume excess
  d. Risk for fluid volume excess.

REFERRALS

- Make appropriate referrals to home health or community social services for assistance with resources such as meals, meal preparation and food delivery, IV infusions and access, enteral feedings, and homemaker or home health aide services to help with ADLs.

COMMUNITY AGENCIES AND OTHER SOURCES OF HELP

- Provide information about companies or agencies that can provide durable medical equipment such as commodes, lift chairs, or hospital beds for purchase, rental, or free of charge.
- Provide a list of sources for supplies such as catheters and drainage bags, measuring devices, tube feeding formulas, and electrolyte replacement drinks.
- Suggest additional sources of information and help such as the American Dietetic Association, the American Heart Association, and the American Lung Association.

PRACTICE GUIDELINES **Facilitating Fluid Intake**

- Explain to the client the reason for the required intake and the specific amount needed. This provides a rationale for the requirement and promotes compliance.
- Establish a 24-hour plan for ingesting the fluids. For a hospitalized or long-term care client, half of the total volume is given during the day shift, and the other half is divided between the evening and night shifts, with most of that ingested during the evening shift. For example, if 2500 mL is to be ingested in 24 hours, the plan may specify 7–3 (1500 mL); 3–11 (700 mL); and 11–7 (300 mL). Try to avoid the ingestion of large amounts of fluid immediately before bedtime to prevent the need to urinate during sleeping hours.
- Set short-term outcomes that the client can realistically meet. Examples include ingesting a glass of fluid every hour while awake or a pitcher of water by lunchtime.
- Identify fluids the client likes and make available a variety of those items, including fruit juices, noncaffeinated soft drinks, and milk (if allowed). Remember that beverages such as coffee, tea, and other caffeinated beverages have a diuretic effect, so their consumption should be limited.
- Help the client to select foods that tend to become liquid at room temperature (e.g., gelatin, ice cream, sherbet, custard), if these are allowed.
- For clients who are confined to bed, supply appropriate cups, glasses, and straws to facilitate adequate fluid intake, and keep fluids within easy reach.
- Make sure fluids are served at the appropriate temperature (i.e., hot fluids hot and cold fluids cold) and according to client preference.
- Encourage clients to participate in maintaining the fluid intake record if possible. This assists them to evaluate the achievement of desired outcomes.
- Be alert to any cultural implications of food and fluids. Some cultures may restrict certain foods and fluids, or temperatures of foods and fluids, and view others as having healing properties.

Implementing

Promoting Wellness

Most individuals rarely think about their fluid, electrolyte, or acid–base balance. They know it is important to drink adequate fluids and consume a balanced diet, but they may not understand the potential effects when this is not done. Nurses can promote clients' health by providing wellness teaching that will help them maintain fluid and electrolyte balance.

Enteral Fluid and Electrolyte Replacement

Fluids and electrolytes can be provided orally in the home or hospital if a client's health permits, meaning that the client is not vomiting, has not experienced an excessive fluid loss, and has an intact gastrointestinal tract and gag and swallow reflexes. Clients who are unable to ingest solid foods may be able to ingest fluids.

Fluid Intake Modifications

Increased fluids (ordered as "push fluids") are often prescribed for clients with actual or potential decreased fluid volume arising, for example, from mild diarrhea or mild to moderate fevers. Guidelines for helping clients increase fluid intake are shown in Practice Guidelines.

Restricted fluids may be necessary for clients who have fluid retention (increased fluid volume) as a result of kidney failure, heart failure, SIADH, or other disease processes. Fluid restrictions vary from "nothing by mouth" to a precise amount ordered by a primary care provider. The restriction of fluids can be difficult for some clients, particularly if they are experiencing thirst. Guidelines for helping clients restrict fluid intake are shown in Practice Guidelines.

Dietary Changes

Specific fluid and electrolyte imbalances may require simple dietary changes. For example, clients receiving potassium-depleting diuretics need to be informed about foods with high potassium content (e.g., bananas, oranges, and leafy greens). Some clients with fluid retention need to avoid foods high in sodium. Most healthy clients can benefit from foods rich in calcium.

PRACTICE GUIDELINES **Helping Clients Restrict Fluid Intake**

- Explain the reason for the restricted intake and how much and what types of fluids are permitted orally. Many clients need to be informed that ice chips, gelatin, and ice cream, for example, are considered fluid.
- Help the client decide the amount of fluid to be taken with each meal, between meals, before bedtime, and with medications. For a hospitalized or long-term care client, half the total volume is usually scheduled during the day shift, when the client is most active, receives two meals, and takes most oral medications. A large part of the remainder is scheduled for the evening shift to permit fluids with meals and evening visitors.
- Identify fluids or fluid-like substances the client likes and make sure that these are provided, unless contraindicated. A client who is allowed only 200 mL of fluid for breakfast, for example, should receive the type of fluid he or she prefers.
- Set short-term goals that make the fluid restriction more tolerable. For example, schedule a specified amount of fluid at one or two hourly intervals between meals. Some clients may prefer fluids only between meals if the food provided at mealtime helps relieve thirst.
- Place allowed fluids in small containers such as a 4-ounce juice glass to allow the perception of a full container.
- Periodically offer the client ice chips as an alternative to water, because ice chips are approximately half of the frozen volume after they melt.
- Provide frequent mouth care and rinses to reduce the thirst sensation.
- Instruct the client to avoid ingesting or chewing salty or sweet foods (hard candy or gum), because these foods tend to produce thirst. Sugarless gum or candy may be an alternative for some clients.
- Encourage the client to participate in maintaining the fluid intake record if possible.

Oral Electrolyte Supplements

Some clients can benefit from oral electrolyte supplements, particularly when a medication is prescribed that affects electrolyte balance, when dietary intake is inadequate for a specific electrolyte, or when fluid and electrolyte losses are excessive, for example, as a result of excessive perspiration.

Corticosteroids and many diuretics can cause too much potassium to be eliminated through the kidneys. For clients taking these medications, potassium supplements may be prescribed. Instruct clients taking oral potassium supplements to take the medication with juice to mask the unpleasant taste and reduce the possibility of gastric distress. Emphasize the importance of taking the medication as prescribed and seeing their primary care provider on a regular basis. Because hyperkalemia can have serious cardiac effects, clients should never increase the amount of potassium being taken without an order to do so. In addition, inform clients that most salt substitutes contain potassium, so it is important to consult with their primary care provider before using salt substitutes.

Individuals who ingest insufficient milk and milk products benefit from calcium supplements. The recommended daily allowance for calcium is 1000 to 1500 mg. It is generally recommended that postmenopausal women take 1500 mg of calcium per day to reduce the risk of osteoporosis. Long-term use of corticosteroid drugs can also cause calcium loss from the bone, and calcium supplements may help reduce this loss. Clients who take supplemental calcium need to maintain a fluid intake of at least 2500 mL per day (unless contraindicated) to reduce the risk of kidney stones, which are commonly composed of calcium salts.

Although routine supplements for other electrolytes generally are not recommended, clients who have poor dietary habits, who are malnourished, or who have difficulty accessing or eating fresh fruits and vegetables may benefit from electrolyte supplements. A daily multiple vitamin with minerals may achieve the desired goal. Individuals who engage in strenuous activity in a warm environment need to be encouraged to replace water and electrolytes lost through excessive perspiration by consuming a sports drink through available commercial fluid and electrolyte solutions.

Liquid nutritional supplements are often given to clients who are malnourished or have poor eating habits. They are used with frequency in older adults to bolster nutritional status and caloric intake. It is very important that clients read product labels accurately to be aware of the contents of the supplement. Some of them are very high in protein and high in potassium, which may be contraindicated in an individual with impaired kidney function.

Parenteral Fluid and Electrolyte Replacement

IV fluid therapy is essential when clients are unable to take sufficient food and fluids orally. It is an efficient and effective method of supplying fluids directly into the intravascular fluid compartment and replacing electrolyte losses. The primary care provider usually orders the IV fluid therapy. The nurse is responsible for administering and maintaining the therapy and for teaching the client and significant others how to continue the therapy at home if necessary.

Intravenous Solutions

IV solutions can be classified as isotonic, hypotonic, or hypertonic. Most IV solutions are isotonic, having the same concentration of solutes as blood plasma. Isotonic solutions are often used to restore vascular volume. Hypertonic solutions have a greater concentration of solutes than plasma; hypotonic solutions have a lesser concentration of solutes. Table 51.11 provides examples of IV solutions and nursing implications.

IV solutions can also be categorized according to their purpose. Nutrient solutions contain some form of carbohydrate (e.g., dextrose, glucose, or levulose) and water. Water is supplied for fluid requirements and carbohydrate for calories and energy. For example, 1 L of 5% dextrose provides 170 calories. Nutrient solutions are useful in

TABLE 51.11 Selected Intravenous Solutions

Type/Examples	Comments/Nursing Implications
ISOTONIC SOLUTIONS 0.9% NACL (normal saline) Lactated Ringer's (a balanced electrolyte solution) 5% dextrose in water (D_5W)	Isotonic solutions such as normal saline (NS) and lactated Ringer's initially remain in the vascular compartment, expanding vascular volume. Assess clients carefully for signs of hypervolemia such as bounding pulse and shortness of breath. D_5W is isotonic on initial administration but provides free water when dextrose is metabolized, expanding intracellular and extracellular fluid volumes. D_5W is avoided in clients at risk for increased intracranial pressure (IICP) because it can increase cerebral edema.
HYPOTONIC SOLUTIONS 0.45% NaCl (half normal saline) 0.33% NaCl (one-third normal saline)	Hypotonic solutions are used to provide free water and treat cellular dehydration. These solutions promote waste elimination by the kidneys. Do not administer to clients at risk for IICP or third-space fluid shift.
HYPERTONIC SOLUTIONS 5% dextrose in normal saline (D_5NS) 5% dextrose in 0.45% NaCl (D_5 1/2NS) 5% dextrose in lactated Ringer's (D_5LR)	Hypertonic solutions draw fluid out of the intracellular and interstitial compartments into the vascular compartment, expanding vascular volume. Do not administer to clients with kidney or heart disease or clients who are dehydrated. Watch for signs of hypervolemia.

preventing dehydration and ketosis but do not provide sufficient calories to promote wound healing, weight gain, or normal growth in children. Common nutrient solutions are 5% dextrose in water (D_5W) and 5% dextrose in 0.45% sodium chloride (dextrose in half-normal saline).

Electrolyte solutions contain varying amounts of cations and anions. Commonly used solutions are normal saline (0.9% sodium chloride solution), Ringer's solution (which contains sodium, chloride, potassium, and calcium), and lactated Ringer's solution (which contains sodium, chloride, potassium, calcium, and lactate). Lactate is metabolized in the liver to form bicarbonate. Saline and balanced electrolyte solutions are commonly used to restore vascular volume, particularly after trauma or surgery. They also may be used to replace fluid and electrolytes for clients with continuing losses, for example, those experiencing gastric suction or wound drainage. Lactated Ringer's solution is an alkalizing solution that may be given to treat metabolic acidosis. Acidifying solutions, in contrast, are administered to counteract metabolic alkalosis. Examples of acidifying solutions are 5% dextrose in 0.45% sodium chloride and 0.9% sodium chloride solution.

Volume expanders are used to increase the blood volume following severe loss of blood (e.g., from hemorrhage) or loss of plasma (e.g., from severe burns, which draw large amounts of plasma from the bloodstream to the burn site). Examples of volume expanders are dextran, plasma, albumin, and Hespan (a synthetic plasma expander).

Peripheral Venous Access Site Selection

The site chosen for peripheral venous access (venipuncture) varies with the client's age, length of time an infusion is to run, the type of solution used, and the condition of veins. For adults, veins in the arm are commonly used; for infants, veins in the scalp and dorsal foot veins are often used. The larger veins of the adult's forearm are preferred over the metacarpal veins of the hand for infusions that need to be given rapidly and for solutions that are hypertonic, are highly acidic or alkaline, or contain irritating medications. The loss of subcutaneous tissue, thinning of the skin, and fragile veins in the older adult can be a challenge for the nurse when performing a venipuncture. It is common practice for the initial venipuncture to be in the most distal portion of the arm because this allows for subsequent venipunctures to move upward. The veins of the hands of the older adult, however, are not the best initial sites for venipuncture because of the loss of subcutaneous tissue and thinning of the skin (Gorski, 2018; Infusion Nurses Society [INS], 2016a).

The metacarpal, basilic, and cephalic veins are common venipuncture sites (Figure 51.14 ■). The ulna and radius act as natural splints at these sites, and the client has greater freedom of arm movement for activities such as eating. Although the antecubital basilic and median cubital veins are convenient, they are usually kept for blood draws, bolus injections of medication, and insertion sites for a peripherally inserted central catheter (PICC) line (Figure 51.14*A*). See Practice Guidelines for vein selection and general tips for easier IV starts.

Figure 51.14 ■ Commonly used venipuncture sites: *A*, arm; *B*, hand. *A* also shows the site used for a peripherally inserted central catheter (PICC).

PRACTICE GUIDELINES **Vein Selection**

- Traditionally, nurses used distal veins of the arm first with subsequent venous access starts to be proximal to the previous site. Current INS recommendations are to "use the venous site most likely to last the full length of the prescribed therapy using the forearm to increase dwell time, decrease pain during dwell time, promote self-care, and prevent accidental removal and occlusions" (Gorski, 2018, p. 276; INS, 2016a, p. S54).
- Use the client's nondominant arm whenever possible.
- Select a vein that is:
  a. Easily palpated and feels soft and full
  b. Naturally splinted by bone
  c. Large enough to allow adequate circulation around the catheter.
- Avoid using veins that are:
  a. In areas of flexion (e.g., the antecubital fossa)
  b. Highly visible, because they tend to roll away from the needle
  c. Damaged by previous use, phlebitis, infiltration, or sclerosis
  d. Continually distended with blood, or knotted or tortuous
  e. In a surgically compromised or injured extremity (e.g., following a mastectomy), because of possible impaired circulation and discomfort for the client.

Historically, nurses used their eyes and hands to locate a suitable vein for a venipuncture. This could be especially challenging in some clients such as older adults, dark-skinned clients whose veins may not be visible, or clients with obesity, because their veins may not be visible or palpable. The use of visualization technology has improved the practice of IV access. The *Infusion Therapy Standards of Practice* (INS, 2016a) state that nurses should "use vascular visualization technology to increase success for patients with difficult venous access" (p. S51). Transillumination devices are available that use light to allow for the location and identification of blood vessels. The client's skin color does not affect the ability to highlight veins. Technology also includes near-infrared (nIR) light technology and ultrasonography for short peripheral catheter placement in adult and pediatric clients with difficult venous access (Gorski, 2018; INS, 2016a, pp. S44–S45).

Intravenous Infusion Equipment

Because equipment varies according to the manufacturer, nurses must become familiar with the equipment used in each particular agency. IV equipment consists of vascular access devices, catheter stabilization devices, site protection devices, solution containers, infusion administration sets, IV filters, and IV poles.

Vascular Access Devices

The *Infusion Therapy Standards of Practice* (INS, 2016a) states that the type of vascular access device (VAD) depends on the client's vascular or venous access needs, which are based on the prescribed therapy, length of treatment, vascular integrity, client preference, and ability and resources available to care for the device (p. S51). All catheters must be radiopaque.

A *short peripheral catheter* is used for usually less than 1 week (check agency policy). It comes in a variety of gauge sizes (a #20 to #24 gauge is used for most infusion therapies) and types (e.g., winged or nonwinged, and over-the-needle) and the tip of the catheter ends in a peripheral vein (INS, 2016a). Over-the-needle catheters (ONCs), also known as angiocatheters, are commonly used for adult clients. The plastic catheter fits over a needle (stylet) used to pierce the skin and vein wall (Figure 51.15 ■). Once inserted into the vein, the needle (stylet) is withdrawn and discarded, leaving the catheter in place. The nurse should use short peripheral catheters equipped with a passive or active safety mechanism to prevent sharps injury. The active safety device requires activation by the nurse, and the passive safety device automatically activates after the stylet is removed from the catheter. Use of the passive safety device is recommended for the prevention of a needlestick injury.

A butterfly or wing-tipped needle with plastic flaps attached to the shaft is sometimes used (Figure 51.16 ■). The flaps are held tightly together to hold the needle securely during insertion; after insertion, they are flattened against the skin and secured with tape. The butterfly

Figure 51.15 ■ Schematic of an over-the-needle short peripheral catheter.

PRACTICE GUIDELINES **General Tips for Easier Insertion of a Short Peripheral Catheter**

- Review the client's medical history. Avoid using an arm affected by hemiplegia or with a dialysis access, on the same side as a mastectomy, or near infections, below previous infiltrations or extravasations, and veins affected by phlebitis.
- Dilate the vein. Ways to do this include (a) dangle the client's arm over the side of the bed to encourage dependent vein filling, (b) ask the client to open and close his or her fist, (c) stroke the vein downward or lightly tap the vein, or (d) apply warm compresses to the site for 10 minutes.
- Make sure the client is positioned comfortably and has been medicated for pain if appropriate. Pain and anxiety stimulate the sympathetic nervous system and trigger vasoconstriction.
- Because of the risk of nerve injuries, as well as discomfort and restriction of movement, hand veins should be a last choice.
- If the ordered IV medication is irritating to veins and therapy is expected to last more than a few days, consult with the IV nurse or medical team to determine whether the client is a candidate for a midline catheter, a peripherally inserted central catheter, or another type of central venous access device.
- Use the smallest gauge catheter that will accommodate the therapy and allow good venous flow around the catheter tip. Use #20- to #24-gauge catheters for routine hydration or intermittent therapy and for transfusion therapy, use #22- to #24-gauge catheters for neonates, pediatric clients, and older adults to minimize insertion-related trauma (INS, 2016a, p. S51).
- Raise the bed or stretcher to a comfortable working height, and keep all equipment within reach. Stabilize the client's hand or arm with your nondominant arm, tucking it under your forearm if necessary to prevent movement.
- Limit your attempts to two. If you are not successful after two tries, ask another nurse to try. Limit total attempts to no more than four (INS, 2016a). If venous sites are not found, use a vascular visualization method.

Clinical Alert!

A short peripheral catheter placed in an emergency situation where aseptic technique has been compromised shall be replaced as soon as possible, preferably within 24 to 48 hours (INS, 2016a, p. S91).

needle is most frequently used for short-term therapy such as with a single-dose IV push medication, or blood sample retrieval. It is not left in place (Gorski, 2018).

A *midline catheter* is 7.6 to 20.3 cm (3 to 8 in.) in length and inserted near the antecubital area into the basilic, cephalic, or brachial veins, with the preference being the basilica vein because of its larger diameter. The catheter tip is advanced no farther than the distal axillary vein in the upper arm; the tip does not enter the central vasculature. The INS classifies the midline catheter as a peripheral catheter. The duration of infusion therapy, however, does differ. For example, a short peripheral catheter is used when the duration of infusion therapy is for less than 1 week; the duration of therapy using a midline catheter can last from 1 to 4 weeks.

A **peripherally inserted central venous catheter (PICC)** is inserted in the basilic or cephalic vein just above or below the antecubital space of the right arm. The tip of the catheter rests in the superior vena cava. These catheters frequently are used for long-term IV access when the client will be managing IV therapy at home.

When long-term IV therapy or parenteral nutrition is anticipated, or a client is receiving IV medications that are damaging to vessels (e.g., chemotherapy), a **central vascular access device (CVAD)** may be inserted. A CVAD is defined by the location of the catheter tip in a *central vein*. The CVAD catheter tip should reside in the lower one-third of the superior vena cava, above the right atrium (Figure 51.17 ■). CVADs may be inserted at a client's bedside or, for longer term access, surgically inserted. They permit freedom of movement for ambulation; however, there is greater risk of complications, including hemothorax or pneumothorax, cardiac perforation, thrombosis, and infection. Assess the client closely for signs and symptoms such as shortness of breath, chest pain, cough, hypotension, tachycardia, and anxiety after the insertion procedure.

Implanted vascular access devices (IVADs) (Figures 51.18 ■ and 51.19 ■) are used for clients with chronic

illness who require long-term IV therapy (e.g., intermittent medications such as chemotherapy, total parenteral nutrition, and frequent blood samples). This type of device is designed to provide repeated access to the central venous system, avoiding the trauma and complications of multiple venipunctures. Using local anesthesia, implantable ports are surgically placed into a small subcutaneous pocket under the skin, usually on the anterior chest near the clavicle, and no part of the port is exposed. The distal end of the catheter is placed in the subclavian or jugular vein.

Special precautions need to be taken with all central lines and venous access ports to ensure asepsis and catheter patency. Nursing care of clients with these devices is outlined in Practice Guidelines.

PRACTICE GUIDELINES Caring for Clients with a Central Vascular Access Device

- After insertion, document the date; the insertion site; the brand, gauge, and catheter length; the location of the catheter tip (verified by x-ray); the length of the external segment; and client teaching. Do not use the access device until correct placement has been verified by x-ray.

SITE CARE

- Use strict aseptic technique (including the use of sterile gloves and mask) when caring for CVADs.
- The frequency of dressing changes is dependent on the dressing material. Transparent semipermeable membrane (TSM) dressings or tape and gauze are acceptable; however, gauze dressings do not allow for visualization of the insertion site and need to be changed every 48 hours or if the site requires visual inspection (Gorski, 2018, p. 404). In contrast, TSM dressings allow for visualization and can be left in place for 5 to 7 days if they remain clean, dry, and intact (INS, 2016b, p. 114). A recent innovation is a TSM dressing that has an integrated gel pad containing chlorhexidine gluconate 2% (CHG). This dressing provides a clear sterile covering for the CVAD, helps secure the device, and provides a continuous application of chlorhexidine at the insertion site. See Figure 1. All dressings should be changed when loose or soiled.
- Assess the site for any redness, swelling, tenderness, or drainage. Compare the length of the external portion of the catheter with its documented length to assess for possible displacement. Report and document any position changes or signs of infection.
- Follow agency protocol for cleaning solutions and types of dressings. Chlorhexidine gluconate is the preferred agent to clean the insertion site.
- Clean the skin around the site with chlorhexidine solution, using a back-and-forth motion for at least 30 seconds (INS, 2016b). Allow the site to air dry.
- Apply a new stabilization device.
- Apply a sterile dressing.

CATHETER CARE AND FLUSHING

- Change the catheter cap as indicated by agency protocol. The catheter hub can be a source of infection. The INS (2016b) states that if using manual disinfection, vigorously scrub with antiseptic wipe using friction and allow to dry completely (p. 111). See agency protocol for length of scrub (e.g., 5 to 60 seconds). Also available are commercial single-use Luer access valve disinfection caps (port protectors). This cap contains isopropyl alcohol, which cleans the needleless connector before access and also protects it from contamination between uses. The cap is twisted onto the needleless connector and left in place until the next access to the connector is needed. The nurse removes and discards the old cap and the connector is ready for use without further wiping. If using a disinfection cap, remove it and discard. Do not reuse this cap. According to INS (2016a), "use of passive disinfection caps containing disinfecting agents has been shown to reduce intraluminal microbial contamination and reduce the rates of central line-associated blood stream infection (CLABSI)" (p. S69). See Figures 2 to 5.
- The solution used and frequency of flushing are determined by agency protocol for the specific type of port being used. If heparin is used as part of the flushing protocol, the concentration should not be in amounts that cause systemic anticoagulation but in the lowest possible concentration to maintain patency (e.g., 10 units/mL).

Continued on page 1376

PRACTICE GUIDELINES **Caring for Clients with a Central Vascular Access Device—*continued***

- Flush the catheter before and after each dose of medication. The initial flush is to assess patency of the catheter, and the flush after administration of the medication is to ensure that the complete dose has entered the bloodstream and to prevent contact between incompatible medications.
- Use a 10-mL syringe to flush the catheter. Never apply force if you feel resistance.
- CVADs need to be locked after the final flush solution to decrease the risk of occlusion (INS, 2016b). Locking a catheter creates a column of fluid inside the lumen to maintain patency. The process for locking a catheter varies depending on the manufacturer of the needleless connector.
- Blood reflux into the catheter lumen after flushing increases the risk of infection. Thus, it is important for the nurse to know the type of needleless connector being used: positive-pressure, negative-pressure, or neutral-displacement needleless connector.

TEACHING

Provide clients with the following instructions:

- Do not allow anyone to take a blood pressure on the arm in which a PICC line is inserted.
- Wear a medical alert tag or bracelet if the device will be in place for a long period of time.
- For a PICC line, activity does not need to be restricted, except that the arm should not be immersed in water. Showering is allowed if the site and catheter are covered by a TSM dressing.
- For an implanted central venous access port, there are no activity restrictions, but the port or catheter tip can become dislodged. Signs of a dislodged catheter tip include pain in the neck or ear on the affected side, swishing or gurgling sounds, or palpitations; signs of a dislodged port include free movement of the port, swelling, or difficulty accessing the port. If any of these occur, or if symptoms of infection develop, notify the primary care provider immediately.

Safety Alert! SAFETY

2019 The Joint Commission National Patient Safety Goals

Goal 7: Reduce the risk of healthcare-associated infections.

Goal 7.04.01: Implement evidence-based practices to prevent central line–associated bloodstream infections. This requirement covers short- and long-term central venous catheters and peripherally inserted central catheter (PICC) lines.

- Implement policies and practices aimed at reducing the risk of central line–associated bloodstream infections.
- Perform hand hygiene prior to catheter insertion or manipulation.
- Use a standardized protocol to disinfect catheter hubs and injection ports before accessing the ports.

Catheter Stabilization Devices

Securing or stabilizing an IV catheter helps decrease movement of the catheter at the insertion site, which helps prevent the catheter from being dislodged and other complications such as infiltration, phlebitis, and infection (Gorski, 2018). The INS standards (2016a) recommend the use of manufactured catheter stabilization devices (Figure 51.20 ■) over other methods such as sterile tapes and surgical strips.

Site Protection Devices

Site protection refers to the use of methods or products that protect the catheter site (Gorski, 2018, p. 233). For example, a clear plastic protector placed over the site can prevent accidental snagging of the catheter hub or the IV line (Figure 51.21 ■). It may be needed for clients who are confused or have cognitive deficits.

EVIDENCE-BASED PRACTICE

Evidence-Based Practice

Is There a Difference in Rate of Infection Among Types of CVAD Dressings?

The use of dressing and securement products is important in the prevention of CVAD complications (e.g., infection, dislodgement). There are many CVAD dressings and securements available to clinicians. The diversity of available dressings and securements makes evidence-based decision-making difficult. The ideal CVAD dressing should provide barrier protection from infection, provide securement to prevent accidental removal or dislodgement, be comfortable for the client, be easy to use, and be cost effective. There is no consensus on the best type of dressing to use with CVADs in spite of more than 2 decades of research. As a result, Ullman et al. (2016) conducted a study to compare available dressings and securement devices for CVADs in terms of infection, skin irritation, failed catheter securement, dressing condition, and mortality (p. 180).

The researchers conducted a Cochrane systematic review that included all randomized controlled trials that evaluated the effects of CVAD dressings and securement devices. The results included 22 studies for meta-analysis. The review found no clear evidence linking gauze and tape and standard polyurethane with skin irritation, failed catheter securement, dressing condition or durability, and mortality. The review did find that there is high-quality evidence that the use of medication-impregnated dressing products (e.g., patch or whole dressing) reduces the incidence of CVAD-related bloodstream infection in comparison with all other dressing types (p. 192). There was not enough research for the authors to make recommendations about CVAD security using the different dressing and securement products.

Implications

The evidence of the effectiveness of chlorhexidine gluconate–impregnated dressing in reducing infection mainly came from studies in intensive care unit (ICU) settings. The authors point to the need for more high-quality research especially as new products become available. More evidence is needed to support effective clinical decision-making.

Figure 51.20 ■ Manufactured catheter stabilization device.

Figure 51.21 ■ IV site protection device.

Figure 51.22 ■ A plastic intravenous solution container.

Solution Containers

Solution containers are available in various sizes (50, 100, 250, 500, or 1000 mL); the smaller containers are often used to administer medications. Most solutions are currently dispensed in plastic containers (Figure 51.22 ■). However, glass bottles may need to be used if the administered medications are incompatible with plastic. Glass bottles require an air vent so that air can enter the bottle and replace the fluid that enters the client's vein. Some bottles contain a tube that serves as a vent; other containers require a vent on the administration set. Air vents usually have filters to prevent contamination from the air that enters the container. Air vents are not required for plastic solution bags, because the bags collapse under atmospheric pressure when the solution enters the vein.

It is essential that the solution be sterile and in good condition, that is, clear. Cloudiness, evidence that the container has been opened previously, or leaks indicate possible contamination. Always check the expiration date on the label. Return any questionable or contaminated solutions to the pharmacy or IV therapy department.

Clinical Alert!

Do not write directly on a plastic IV bag with a ballpoint pen (may puncture the bag) or indelible marker (may absorb through the bag into the solution).

Infusion Administration Sets

Infusion administration sets (also called administration infusion sets) consist of an insertion spike, a drip chamber, a roller valve or screw clamp, tubing with secondary ports, and a protective cap over the connecter to the IV catheter (Figure 51.23 ■). The insertion spike is kept sterile and inserted into the solution container when the equipment is set up and ready to start. The drip chamber permits a predictable amount of fluid to be delivered. A macrodrip drip chamber delivers between 10 and 20 drops (abbreviated gtts) per milliliter of solution. The specific amount is written on the package. Microdrip sets deliver 60 drops per milliliter of solution (Figure 51.24 ■). Many infusion sets include an in-line filter to trap air, particulate matter, and microbes. A special infusion set may be required if the IV flow rate will be regulated by an infusion pump.

Figure 51.23 ■ A standard IV infusion administration set.

A

B

Figure 51.24 ■ Infusion set spikes and drip chambers: *A*, nonvented macrodrip and *B*, nonvented microdrip.

Most infusion sets include one or more injection ports for administering IV medications or secondary infusions. Needleless systems are used because they reduce the risk of needlestick injury and contamination of the IV line. The needleless ports can be accessed with a syringe that has a Luer-Lok to administer medications (Figure 51.25 ■). When more than one solution needs to be infused at the same time, *secondary sets* such as the piggyback IV setups are used. Another variation is a *volume-control set*, which is used if the volume of fluid or medication administered is to be carefully controlled (see Chapter 35 ∞).

Rather than using a continuous infusion, an intermittent infusion lock may be created by attaching a sterile needleless connector (also called an injection cap or port) (Figure 51.26 ■) to an existing IV catheter hub. This keeps the venous vascular access available for the administration of intermittent or emergency medications. The device is commonly referred to as a saline lock because periodic

Figure 51.25 ■ Needleless injection port on an IV infusion administration set.

Figure 51.26 ■ A needleless connector.

injection with saline is used to keep blood from coagulating within the tubing.

Intravenous Filters

IV filters are used to remove air and particulate matter from IV infusions and to reduce the risk of complications (e.g., infusion-related phlebitis) associated with routine IV therapies (Figure 51.27 ■). Use filters according to the manufacturer's directions for use and the filtration requirements of the infusion therapy solution or medication (INS, 2016a). When using filters, the nurse must remember that the filter should never be considered a substitute for quality care and meticulous technique.

Intravenous Poles

IV poles (rods) are used to hang the solution container. Some poles are attached to hospital beds; others stand on the floor or hang from the ceiling. Still others are floor models with casters that can be pushed along when a client is up and walking. In the home, plant hangers or robe hooks (even kitchen cabinet knobs or an S-hook over the top of a door) may be used to hang solution containers. The height of most poles is adjustable. The higher the solution container, the greater the force of the solution as it enters the client and the faster the rate of flow.

Figure 51.27 ■ Two types of IV filters.

Starting an Intravenous Infusion

Although the primary care provider is responsible for ordering IV therapy for clients, nurses initiate, monitor, and maintain the prescribed IV infusion. This is true not only in hospitals and long-term care facilities but increasingly in community-based settings such as clinics and clients' homes.

Before starting an infusion, the nurse determines the following:

- The type and amount of solution to be infused
- The exact amount (dose) of any medications to be added to a compatible solution
- The rate of flow or the time over which the infusion is to be completed.

If solutions are prepared by the pharmacy or another department, the nurse must verify that the solution supplied exactly matches that which the primary care provider ordered.

Understanding the purpose for the infusion is as important as assessing the client. For example, a nurse should question an order for 5% dextrose in water at 150 mL/h if the client has peripheral edema and other signs of fluid overload.

To start an IV infusion and insert a short peripheral catheter, see Skill 51.1.

Starting an Intravenous Infusion and Inserting a Short Peripheral Catheter

SKILL 51.1

Before preparing the infusion, the nurse first verifies the primary care provider's order indicating the type of solution, the amount to be administered, the rate of flow or time over which the infusion is to be completed, and any client allergies (e.g., to tape or povidone-iodine).

PURPOSES

- To supply fluid when clients are unable to take in an adequate volume of fluids by mouth
- To provide salts and other electrolytes needed to maintain electrolyte balance
- To provide glucose (dextrose), the main fuel for metabolism
- To provide water-soluble vitamins and medications
- To establish a lifeline for rapidly needed medications

ASSESSMENT

Assess

- Vital signs (pulse, respiratory rate, and BP) for baseline data.
- Allergy to latex (e.g., tourniquet), tape, or iodine.
- Bleeding tendencies.
- Disease or injury to extremities.
- Status of veins to determine appropriate vascular access site. Avoid sites that have been used recently. **Rationale:** *Recently used sites will be more prone to complications and discomfort*.
- Determine if the client is right- or left-handed. **Rationale:** *Do not use the dominant hand if possible*. If venous sites are not found, avoid blind venipuncture and use a vascular visualization method (INS, 2016b, p. 53).
- The agency policy about clipping hair in the area before a venipuncture. Shaving is not recommended because of the possibility of nicking the skin and subsequent infection.

Continued on page 1380

Starting an Intravenous Infusion and Inserting a Short Peripheral Catheter—*continued*

SKILL 51.1

PLANNING

Prior to initiating the IV infusion, consider how long the client is likely to have the IV, what kinds of fluids will be infused, and what medications the client will be receiving or is likely to receive. These factors may affect the choice of vein and catheter size. Review the client record regarding previous infusions. Note any complications and how they were managed. Consider using local anesthetic agents to reduce the pain and discomfort of catheter insertion.

Assignment

Due to the need for knowledge of anatomy and use of sterile technique, IV infusion therapy is not assigned to AP. AP may care for clients receiving IV therapy, and the nurse must ensure that the AP knows how to perform routine tasks such as bathing and positioning without disturbing the IV. The AP should also know what complications or adverse signs, such as leakage, should be reported to the nurse.

In many states, a licensed practical nurse or licensed vocational nurse with special IV therapy training may start IV infusions. Check the state's nurse practice act.

Equipment

Substitute appropriate supplies if the client has tape, antiseptic, or latex allergies.

- Infusion set
- Extension tubing (optional)
- Sterile parenteral solution
- IV pole
- Nonallergenic tape
- Clean gloves (sterile gloves are needed for site palpation after skin antisepsis)
- Single-use and latex-free tourniquet
- Antiseptic swabs such as 10% povidone-iodine or 2% chlorhexidine gluconate with alcohol or 70% isopropyl alcohol. The preferred antiseptic is alcoholic chlorhexidine solution as it has a residual effect on the skin for up to 48 hours (Gorski, 2018, p. 287).
- IV catheter with passive safety mechanism. **Rationale:** *The passive design automatically retracts the needle avoiding needlestick injury*. Choose an IV catheter of the appropriate type and size based on the size of the vein and the purpose of the IV. A #20- to #24-gauge catheter is indicated for most adults. Use the *smallest* gauge that can be used for the prescribed IV infusion. Always have an extra catheter and ones of different sizes available.
- Vein visualization device, if needed
- Sterile gauze dressing or transparent semipermeable membrane (TSM) dressing (preferred)
- Stabilization device
- IV protection device
- Splint, if required
- Towel or bed protector
- Local anesthetic (optional and per agency policy)
- Electronic infusion device or pump (The nurse decides what device is needed as appropriate to the client's condition.)

IMPLEMENTATION

Preparation

- If possible, select a time to perform the venipuncture that is convenient for the client. Unless initiating IV therapy is urgent, provide any scheduled care before establishing the infusion to minimize excessive movement of the affected limb. **Rationale:** *Moving the limb after the infusion has been established could dislodge the catheter*.
- Make sure that the client's clothing or gown can be removed over the IV apparatus if necessary. Many agencies provide special gowns that open over the shoulder and down the sleeve for easy removal.
- Visitors or family members may be asked to leave the room if desired by the nurse or the client.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how to participate. Venipuncture can cause discomfort for a few seconds, but there should be no ongoing pain after insertion. If possible, explain how long the IV will need to remain in place and how it will be used.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Position the client appropriately.
   - Assist the client to a comfortable position, either sitting or lying. Expose the limb to be used but provide for client privacy.

   (*Note*: Steps 4 through 10 may be performed outside of the client's room and then the system transported to the client's bedside.)
4. Apply a medication label to the solution container if a medication is added.
   - In most agencies, medications are added and labels are applied to IV containers in the pharmacy; if they are not, apply the label upside down on the container. **Rationale:** *The label is applied upside down so it can be read easily when the container is hanging up*.
5. Open and prepare the infusion set.
   - Remove tubing from the package and straighten it out.
   - Slide the tubing clamp along the tubing until it is just below the drip chamber to facilitate its access.
   - Close the clamp.
   - Leave the ends of the tubing covered with the plastic caps until the infusion is started. **Rationale:** *This will maintain the sterility of the ends of the tubing*.
   - Consider using extension tubing between the peripheral catheter and needleless connector. **Rationale:** *This reduces catheter manipulation, which can cause phlebitis*. Flush the extension tubing also.
6. Spike the solution container.
   - Expose the insertion site of the bag or bottle by removing the protective cover.
   - Remove the cap from the spike and insert the spike into the insertion site of the bag or bottle. ❶
7. Hang the solution container on the pole.
   - Adjust the pole so that the container is suspended about 1 m (3 ft) above the client's head. **Rationale:** *This height is needed to enable gravity to overcome venous pressure and facilitate flow of the solution into the vein*.
8. Partially fill the drip chamber with solution.
   - Squeeze the chamber gently until it is half full of solution. ❷ **Rationale:** *The drip chamber is partially filled with solution to prevent air from moving down the tubing*.
9. Prime the tubing as described next. The term *prime* means "to make ready" but in common use refers to flushing the tubing to remove air.
   - Remove the protective cap and hold the tubing over a container. Maintain the sterility of the end of the tubing and the cap.

Starting an Intravenous Infusion and Inserting a Short Peripheral Catheter—*continued*

SKILL 51.1

❶ Inserting the spike.

❷ Squeezing the drip chamber.

- Release the clamp and let the fluid run through the tubing until all bubbles are removed. Tap the tubing if necessary with your fingers to help the bubbles move. **Rationale:** *The tubing is primed to prevent the introduction of air into the client. Air bubbles smaller than 0.5 mL usually do not cause problems in peripheral lines*.
- Reclamp the tubing and replace the tubing cap, maintaining sterile technique.
- If an infusion control pump, electronic device, or controller is being used, follow the manufacturer's directions for inserting the tubing and setting the infusion rate.

10. Perform hand hygiene again just prior to client contact.

11. Select the venipuncture site.

- Use the client's nondominant arm, unless contraindicated (e.g., mastectomy, fistula for dialysis). Identify possible venipuncture sites by looking for veins that are relatively straight. The vein should be palpable, but may not be visible, especially in clients with dark skin. Consider the catheter length; look for a site sufficiently distal to the wrist or elbow such that the tip of the catheter will not be at a point of flexion. **Rationale:** *Sclerotic veins may make initiating and maintaining the IV difficult. Joint flexion increases the risk of irritation of vein walls by the catheter*. Choose the site most likely to last the full length of the IV therapy, which most likely will be using a vein in the forearm (Gorski, 2018, p. 176).
- Check agency protocol about shaving if the site is very hairy. Shaving is not recommended. **Rationale:** *Shaving can cause microabrasions that can increase the risk of infection*.
- Place a towel or bed protector under the extremity to protect linens (or furniture if in the home).

12. Dilate the vein.

- Place the extremity in a dependent position (lower than the client's heart). **Rationale:** *Gravity slows venous return and distends the veins. Distending the veins makes it easier to insert the needle properly*.
- Apply a tourniquet 15 to 20 cm (6 to 8 in.) above the venipuncture site. ❸ Explain that the tourniquet will feel tight. **Rationale:** *The tourniquet must be tight enough to obstruct venous flow but not so tight that it occludes*

❸ Two types of tourniquets.

Continued on page 1382

Starting an Intravenous Infusion and Inserting a Short Peripheral Catheter—*continued*

SKILL 51.1

arterial flow. Obstructing arterial flow inhibits venous filling. If a radial pulse can be palpated, the arterial flow is not obstructed.
- Use the tourniquet on only one client. **Rationale:** *This avoids cross-contamination to other clients*. Be sure to ask if the client has a latex allergy.
- For older adults with fragile skin, instead of applying a tourniquet, place the arm in a dependent position to allow the veins to engorge. **Rationale:** *The tourniquet can cause tissue damage and may not be needed to allow the vein to dilate*.
- If the vein is not sufficiently dilated:
  a. Massage or stroke the vein distal to the site and in the direction of venous flow toward the heart. **Rationale:** *This action helps fill the vein*.
  b. Encourage the client to clench and unclench the fist. **Rationale:** *Contracting the muscles compresses the distal veins, forcing blood along the veins and distending them*.
  c. Lightly tap the vein with your fingertips. **Rationale:** *Tapping may distend the vein*.
- If the preceding steps fail to distend the vein so that it is palpable, remove the tourniquet and wrap the extremity in a warm towel for 10 to 15 minutes. **Rationale:** *Heat dilates superficial blood vessels, causing them to fill*. Then repeat steps to dilate the vein.
- If no venous sites are visible or easily palpated, use vein visualization technology to improve insertion success (INS, 2016b).

13. Remove the tourniquet while preparing the insertion site.

14. Minimize insertion pain as much as possible.
- Although the pain of insertion should be brief, prevention can and should be offered. Transdermal analgesic creams (e.g., EMLA, Synera) may be used, depending on policy. The length of time for the topical analgesic to take effect will vary depending on the agent used (Gorski, 2018).
- If desired and permitted by policy, inject 0.3 mL of 1% lidocaine (without epinephrine) intradermally over the site where you plan to insert the IV catheter. (Be sure to first apply gloves and clean the skin site as described in step 15.) Allow 15 to 30 seconds for the anesthetic to take effect (Gorski, 2018, p. 284).

15. Apply clean gloves and clean the venipuncture site. **Rationale:** *Gloves protect the nurse from contamination by the client's blood*.
- Clean the skin with soap and water if visibly soiled. Remove excess hair if necessary using scissor or surgical clippers.
- Clean the skin at the site of entry with a topical single-use antiseptic swab. The preferred antiseptic is chlorhexidine gluconate-alcohol solution; if there is a contraindication, 70% alcohol, tincture of iodine, or an iodophor may be used (Gorski, 2018, p. 287). Check for allergies to iodine or shellfish before cleansing skin with Betadine or iodine products.
- When using chlorhexidine solution (preferred), use a back-and-forth motion for a minimum of 30 seconds to scrub the insertion site and surrounding area (INS, 2016b, p. 59). Allow the site to completely air dry before inserting the catheter. Do *not* fan, blow on, or wipe the skin.
- If using povidone-iodine, apply using applicator and allow to remain on the skin for 1.5 to 2 minutes or longer to completely dry for adequate antisepsis. The use of concentric circles or a back-and forth motion for this skin preparation has not been studied (INS, 2016b, p. 59). Alcohol should not be applied after the application of povidone-iodine preparation because it counteracts the effects of povidone-iodine (Gorski, 2018, p. 288).

16. Reapply a tourniquet above the intended venipuncture site or use vein visualization technology, if needed.
- If vein palpation is necessary after application of skin antiseptic, apply sterile gloves.

17. Insert the catheter and initiate the infusion.
- Remove the catheter assembly from its sterile packaging. Review instructions for using the catheter because a variety of needle safety devices are manufactured. Remove the cover of the needle (stylet).
- Use the nondominant hand to pull the skin taut below the entry site. **Rationale:** *This stabilizes the vein and makes the skin taut for needle entry. It can also make initial tissue penetration less painful*.
- Holding the over-the-needle catheter at a 15- to 30-degree angle with needle (stylet) bevel up, insert the catheter through the skin and into the vein. A sudden lack of resistance is felt as the needle (stylet) enters the vein. Use a slow, steady insertion technique and avoid jabbing or stabbing motions.
- Once blood appears in the lumen or clear "flashback" chamber of the needle, lower the angle of the catheter until it is almost parallel with the skin, and advance the needle (stylet) and catheter approximately 0.5 to 1 cm (about 1/4 in.) farther into the vein. ④ Holding the needle assembly steady, advance the catheter forward off the stylet until the hub is at the venipuncture site. The exact technique depends on the type of device used. **Rationale:** *The catheter is advanced to ensure that it, and not just the stylet, is in the vein*.
- If there is no blood return, try redirecting the catheter assembly again toward the vein. If the stylet has been withdrawn from the catheter even a small distance, or the catheter tip has been pulled out of the skin, the catheter must be discarded and a new one used. **Rationale:** *Reinserting the stylet into the catheter can result in damage or slicing of the catheter. A catheter that has been removed from the skin is considered contaminated and cannot be reused*.
- If blood begins to flow out of the vein into the tissues as the catheter is inserted, creating a hematoma, the insertion has not been successful. This is sometimes referred to as a blown vein. Immediately release the tourniquet and remove the catheter, applying pressure over the insertion site with dry gauze. Attempt the venipuncture in another site, in the opposite arm if possible. **Rationale:** *Placing the tourniquet back on the same arm above the unsuccessful site may cause it to bleed. Placing the IV below the unsuccessful site could result in infusing fluid into the already punctured vein, causing it to leak*.

④ Blood is noted in the flashback chamber once the stylet has entered the vein.

Starting an Intravenous Infusion and Inserting a Short Peripheral Catheter—*continued*

- Release the tourniquet.
- Put pressure on the vein proximal to the catheter to eliminate or reduce blood oozing out of the catheter. Stabilize the hub with thumb and index finger of the nondominant hand.
- Remove the protective cap from the distal end of the tubing and hold it ready to attach to the catheter, maintaining the sterility of the end.
- Stabilize the catheter hub and apply pressure distal to the catheter with your finger. ❺ **Rationale:** *This prevents excessive blood flow through the catheter*.
- Carefully remove the stylet, engage the needle safety device if it does not engage automatically, and attach the end of the infusion tubing to the catheter hub. Place the stylet directly into a sharps container. If this is not within reach, place the stylet into its original package and dispose in a sharps container as soon as possible. Consider use of an extension set to reduce catheter manipulation. If used, prime the extension set prior to inserting the short peripheral catheter.
- Initiate the infusion or flush the catheter with sterile normal saline. ❻ **Rationale:** *Blood must be removed from the catheter lumen and tubing immediately. Otherwise, the blood will clot inside the lumen*. Watch closely for any signs that the catheter is infiltrated. **Infiltration** is when the tip of the IV catheter is outside the vein and the fluid is entering the tissues instead of the intended vascular route. It is manifested by localized swelling, coolness, pallor, and discomfort at the IV site. **Rationale:** *Inflammation or infiltration necessitates removal of the IV needle or catheter to avoid further trauma to the tissue*.

18. Stabilize the catheter and apply a dressing.

- Secure the catheter according to the manufacturer's instructions and agency policy. Several methods are used to stabilize the catheter including the use of a dressing and securement device. If tape is used, it must be sterile tape or surgical strips and they should be applied only to the catheter adapter and not placed directly on the catheter–skin junction site. Use of a manufactured stabilization device is preferred (INS, 2016a).
- Apply a TSM dressing over the insertion site. ❼ The TSM allows for continuous assessment of the site. Do not use ointment of any kind under a TSM dressing. Additional tape may be used to secure the IV catheter below the TSM, if necessary. Do not place tape on the TSM dressing.
- Label the dressing with the date and time of insertion, gauge, and your initials. ❽
- Apply an IV site protection device, if available. Protection devices are available that help prevent dislodgement of the IV catheter and still provide easy assessment of the IV site.
- Loop the tubing and secure it with tape. **Rationale:** *Looping and securing the tubing prevent the weight of the tubing or any movement from pulling on the needle or catheter*.

❺ Stabilize the catheter hub and occlude the vein with finger(s) while removing the stylet.

❻ The catheter is stabilized while gently flushing it to determine patency.

❼ Applying a sterile one-piece IV stabilization and TSM dressing device.

❽ IV site is labeled with date, time, size of catheter, and initials.

Continued on page 1384

SKILL 51.1

Starting an Intravenous Infusion and Inserting a Short Peripheral Catheter—*continued*

19. Discard the tourniquet.
- Remove and discard gloves.
- Perform hand hygiene.

20. Ensure appropriate infusion flow.
- Apply a padded arm board to splint the joint if needed.
- Adjust the infusion rate of flow according to the order.

21. Label the IV tubing.
- Label the tubing with the date and time of attachment and your initials. 9 This labeling may also be done when the infusion is started. **Rationale:** *The tubing is labeled to ensure that it is changed at regular intervals (i.e., according to agency policy).*

9 Tubing labeled with date, time, and nurse's initials.

22. After IV insertion, complete the following client teaching:
- Any limitations as to movement or mobility and protection of the site
- Signs and symptoms to report to the nurse
- Alarms if an electronic infusion device is being used
- Infection prevention precautions, including hand hygiene by all healthcare providers who provide care (Gorski, 2018, p. 296).

23. Document all assessments and interventions.
- Record the venipuncture on the client's chart. Some agencies provide a special form for this purpose. Include the date and time of the venipuncture; use of visualization technology as appropriate; type, length, and gauge of the needle or catheter; venipuncture site, how many attempts were made, amount and type of solution used, including any additives (e.g., kind and amount of medications); flow rate; the type of dressing applied; the client's general response; and client education.

SAMPLE DOCUMENTATION

1/15/2020 0600 Inserted 20-gauge, 1-inch angiocath in the right cephalic vein 4 inches above the (L) wrist on first attempt. StatLock used to stabilize catheter and TSM dressing applied. IV infusing at 125 mL/h. Explained reason for IV. Verbalized understanding. A. Luis, RN

EVALUATION

- Regularly check the client for intended and adverse effects of the infusion.
- Perform follow-up based on findings or outcomes that deviated from expected or normal for the client. Compare findings to previous data if available.
- At least every 4 hours, check the skin status at IV site (warm temperature and absence of pain, redness, or swelling), status of the dressing, the client's ability to perform self-care activities, and the client's understanding of any mobility limitations.
- Report significant deviations from normal to the primary care provider.

Regulating and Monitoring Intravenous Infusions

An important nursing function is to regulate the flow rate of an IV infusion. Orders for IV infusions may take several forms, for example "3000 mL over 24 hours," "1000 mL every 8 hours × 3 bags," or "125 mL/h until oral intake is adequate." The nurse initiating the IV calculates the correct flow rate, regulates the infusion, and monitors the client's responses. Unless an infusion control device is used, the nurse manually regulates the drops per minute of flow using the roller clamp to ensure that the prescribed amount of solution will be infused in the correct time span. Problems that can result from incorrectly regulated infusions include hypervolemia, hypovolemia, electrolyte imbalances, and medication complications.

The number of drops delivered per milliliter of solution varies with different brands and types of infusion sets. This rate, called the **drop factor**, is printed on the package of the infusion set. Macrodrops commonly have drop factors of 10, 12, 15, or 20 drops/mL; the drop factor for microdrip sets is always 60 drops/mL (see Figure 51.24 earlier).

To calculate flow rates, the nurse must know the volume of fluid to be infused and the specific time for the infusion. Two commonly used methods of indicating flow rates are designating (1) the number of milliliters to be administered in 1 hour (mL/h) or (2) the number of drops to be given in 1 minute (gtt/min).

Occasionally, the IV rate order will read "keep vein open" (KVO) or "to keep open" (TKO). This order does

not provide adequate direction for the nurse unless agency policy specifies the milliliters per hour equivalent for this order. Generally, the KVO rate is less than 50 mL/h. Some IV pumps have a keep-open rate choice built in. If the IV is not on this type of pump and no policy exists, contact the primary care provider for clarification.

Milliliters per Hour

Hourly rates of infusion can be calculated by dividing the total infusion volume by the total infusion time in hours. For example, if 3000 mL is infused in 24 hours, the number of milliliters per hour is

$$\frac{3000\text{ mL (total infusion volume)}}{24\text{ h (total infusion time)}} = 125\text{ mL/h}$$

Nurses need to check infusions at least every hour to ensure that the indicated milliliters per hour have infused and that IV patency is maintained.

Drops per Minute

The nurse who begins an infusion must regulate the drops per minute to ensure that the prescribed amount of solution will infuse. Drops per minute are calculated by the following formula:

$$\text{Drops per minute} = \frac{\text{Total infusion volume} \times \text{drop factor}}{\text{Total time of infusion in minutes}}$$

If the requirements are 1000 mL in 8 hours and the drip factor is 20 drops/mL, the drops per minute should be

$$\frac{1000\text{ mL} \times 20}{8 \times 60\text{ min (480 min)}} = 41\text{ drops/min}$$

The nurse regulates the drops per minute by tightening or releasing the IV tubing clamp and counting the drops for 15 seconds, then multiplying that number by 4.

A number of factors influence flow rate (Box 51.6).

Devices to Control Infusions

Historically, the nurse manually regulated the IV rate with the roller clamp on the administration set. Although a roller clamp can still be used, a number of other devices are available to control the rate of an infusion. The term *flow-control device* refers to any manual, mechanical, or electronic infusion device used to regulate the IV flow rate. The *Infusion Therapy Standards of Practice* (INS, 2016a) state that the choice of a flow-control device (e.g., manual flow regulator, elastomeric balloon pump, electronic infusion device) should consider the age and mobility of the client, severity of illness, type of therapy, and healthcare setting (p. S48).

In the acute healthcare setting, electronic infusion devices (EIDs) are predominantly used to regulate the infusion rate at preset limits. They are used for IV infusions that require precise flow control and for client safety. EIDs are powered by electricity or battery and are programmed to regulate the IV flow rate in either drops per minute or milliliters per hour (Figure 51.28 ■). They use positive pressure to deliver the IV solution, provide an accurate flow rate, are easy to use, and have alarms that signal problems with the infusion (e.g., when the solution in the IV bag is low, when there is air in the tubing, or when flow is impeded by an occlusion). The alarms are helpful; however, the nurse must still conduct regular assessment and evaluation of the IV site to ensure safe infusion.

Clinical Alert!

Many EIDs use low infusion pressures, often lower than the pressure of a gravity delivery. As a result, they do not detect infiltration. When an infiltration occurs, the inline pressure may drop and not trigger an alarm. Thus, it is important for the nurse to assess for infiltration for clients with EIDs (Gorski, 2018, p. 252).

Another type of flow-control device is the multichannel pump. This type of pump can deliver several medications and fluids at the same time, at multiple rates, from bags, bottles, or syringes (Gorski, 2018, p. 249). The multichannel pump usually has two to four

BOX 51.6 Factors Influencing Flow Rates

- *The position of the forearm.* Sometimes a change in the position of the client's arm decreases flow. Slight pronation, supination, extension, or elevation of the forearm on a pillow can increase flow.
- *The position and patency of the tubing.* Tubing can be obstructed by the client's weight, a kink, or a clamp closed too tightly. The flow rate also diminishes when part of the tubing dangles below the puncture site.
- *The height of the infusion bottle.* Elevating the height of the infusion bottle a few inches can speed the flow by creating more pressure.
- *Possible infiltration or fluid leakage.* Swelling, a feeling of coldness, and tenderness at the venipuncture site may indicate infiltration.
- *Relationship of the size of the angiocath to the vein.* A catheter that is too large may impede the infusion flow.

Figure 51.28 ■ An EID.
Jatuporn Amorntangsati/123RF.

channels with each channel being programmed independently (Figure 51.29 ■).

Newer systems, called smart pumps, are EIDs with a computer system. They are programmable and include drug libraries with dose rate calculators, automatic flushing between medications, dual or triple simultaneous line control, memory, multiple alarm settings, air in line, pressure and resistance, battery, schedule reminders, volume settings down to 0.1 mL, panel locks, and digital displays (Giuliano & Ruppel, 2017, p. 64). Smart pumps have advanced complex IV medication and client safety. However, safety issues still exist. It is important that nurses who use this technology work closely with vendors to make suggestions on how to improve the technology.

Mechanical flow-control devices are often used to regulate infusion rates in home care and ambulatory settings. Examples of these nonelectric methods include use of a Dial-A-Flo in-line gravity control device and the elastomeric pump. The Dial-A-Flo in-line device (Figure 51.30 ■) is a manual regulator that controls the amount of fluid to be administered. The Dial-A-Flo may be used in situations where a pump is not available or required, but prevention of fluid overload is important. The nurse presets the volume to be infused by rotating the dial to the desired rate. It is important for the nurse to remember to verify the flow rate by counting the drops.

The elastomeric infusion pump (Figure 51.31 ■), a nonelectric portable disposable pump, is prefilled with a medication and connects to the client's needleless connector. It is a lightweight, disposable pump that delivers medications at a controlled rate. The medication is held in a reservoir (balloon) that is inside a rigid, transparent container. The balloon exerts positive pressure to administer the medication into the tubing that is attached to the client's vascular access device. It has

Figure 51.29 ■ Programmable multichannel infusion pump.

A

B

Figure 51.30 ■ *A*, The Dial-A-Flo in-line gravity control device; *B*, the manual rate-flow regulator.

Figure 51.31 ■ Examples of elastomeric infusion pumps often used in home settings.

an integrated flow restrictor that controls the flow rate (Gorski, 2018, p. 241). The elastomeric infusion pump is portable and can be put in a loose pocket or bag while infusing, allowing the client to be mobile. When the infusion is finished, the entire device is discarded. The elastomeric pump provides ease of use in the home care setting.

Clinical Alert!

A flow-rate-control device should be used when administering IV fluid to older adults or pediatric clients. Both of these age groups are especially at risk for complications of fluid overload, which can occur with rapid infusion of IV fluids.

Skill 51.2 outlines the steps involved in monitoring an IV infusion.

Monitoring an Intravenous Infusion

SKILL 51.2

PURPOSES

- To maintain the prescribed flow rate
- To prevent complications associated with IV therapy

ASSESSMENT

Assess

- Appearance of infusion site; patency of system
- Type of fluid being infused and rate of flow
- Response of the client

PLANNING

Review the client record regarding previous infusions and use of infusion devices. Note any complications and how they were managed. Gather the pertinent data.

- From the order, determine the type and sequence of solutions to be infused.
- Determine the rate of flow and infusion schedule.

Assignment

Due to the need for sterile technique and technical complexity, inspection of IV sites and regulation of IV rates is not assigned to AP. AP may care for clients with such devices, and the nurse must ensure that the AP knows what complications or adverse signs should be reported to the nurse.

In many states, a licensed practical nurse or licensed vocational nurse with special IV therapy training may manage infusions. Check the state's nurse practice act.

Equipment

None

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how to participate.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Position the client appropriately.
   - Assist the client to a comfortable position, either sitting or lying.
   - Expose the IV site but provide for client privacy.
4. Ensure that the correct solution is being infused.
   - Compare the label on the container (including added medications) to the order. If the solution is incorrect, slow the rate of flow to a minimum to maintain the patency of the catheter. If the infusing solution is contraindicated for the client, stop the infusion and saline-lock the catheter. **Rationale:** *Just stopping the infusion may allow a thrombus to form in the IV catheter. If this occurs, the catheter must be removed and another venipuncture performed before the infusion can be resumed. Because IV tubing contains approximately 12 to 15 mL, it may be desirable to prevent even this much additional incorrect solution to infuse when the correct IV solution container is hung on existing tubing. In this case, all tubing should be removed until new tubing, primed with the correct solution, can be started*.
   - Change the solution to the correct one, using new tubing if indicated.
   - Document and report the error according to agency protocol.
5. Observe the rate of flow every hour.
   - Compare the rate of flow regularly, for example, every hour, against the infusion schedule. **Rationale:** *Infusions that are off schedule can be harmful to a client*. To read the volume in an IV bag, pull the edges of the bag apart at the level of the fluid and read the volume remaining. **Rationale:** *Stretching the bag allows the fluid meniscus to fall to the proper level*.
   - Observe the position of the solution container. If it is less than 1 m (3 ft) above the IV site, readjust it to the correct height of the pole. **Rationale:** *If the container is too low with a gravity IV infusion, the solution may not flow into the vein because there is insufficient gravitational pressure to overcome the pressure of the blood within the vein*.
   - If too much fluid has infused in the time interval, check agency policy. The primary care provider may need to be notified.

Continued on page 1388

Monitoring an Intravenous Infusion—*continued*

SKILL 51.2

- In some agencies, you will slow the infusion to less than the ordered rate so that it will be completed at the planned time. **Rationale:** *Solution administered too quickly may cause a significant increase in circulating blood volume (which is about 6 L in an adult). Hypervolemia may result in pulmonary edema and cardiac failure*. Assess the client for manifestations of hypervolemia and its complications, including dyspnea; rapid, labored breathing; cough; crackles; tachycardia; and bounding pulses.
- In other agencies, if the order is for a specified amount of fluid per hour, the IV may be adjusted to the correct rate and the client monitored for signs of fluid overload.
- If the rate is too slow, adjust the IV to the prescribed rate. Also, check agency policy. Some agencies permit nursing personnel to adjust an IV that is behind time by a specified percentage. Adjustments above this amount may require a primary care provider's order. **Rationale:** *Solution that is administered too slowly can supply insufficient fluid, electrolytes, or medication for a client's needs*.
- If the prescribed rate of flow is 150 mL/h or more, check the rate of flow more frequently, for example, every 15 to 30 minutes.

6. Inspect the patency of the IV tubing and catheter.
- Observe the drip chamber. If it is less than half full, squeeze the chamber to allow the correct amount of fluid to flow in.
- Inspect the tubing for kinks or obstructions to flow. Arrange the tubing so that it is lightly coiled and under no pressure. Sometimes the tubing becomes caught under the client's body and the weight blocks the flow.
- Observe the position of the tubing. If it is dangling below the venipuncture, coil it carefully on the surface of the bed. **Rationale:** *The solution may not flow upward into the vein against the force of gravity*.
- Determine catheter position. Some methods include:
  a. Aspirate the catheter for a blood return. Do this slowly and gently.
  b. Lower the solution container below the level of the infusion site and observe for a return flow of blood from the vein. **Rationale:** *A return flow of blood indicates that the needle is patent and in the vein. Blood returns in this instance because venous pressure is greater than the fluid pressure in the IV tubing. Absence of blood return may indicate that the needle is no longer in the vein or that the tip of the catheter is partially obstructed by a thrombus, the vein wall, or a valve in the vein. (Note: With some catheters, no blood may appear even with patency because the soft catheter walls collapse during siphoning.)*
  c. If there is leakage, locate the source. If the leak is at the catheter connection, tighten the tubing into the catheter. If the leak is elsewhere in the tubing, slow the infusion and replace the tubing. Estimate the amount of solution lost, if it was substantial. If the IV insertion site is leaking, the catheter will have to be removed and IV vascular access reestablished at a new site.

7. Inspect the insertion site for fluid infiltration.
- If infiltration is present, stop the infusion and remove the catheter. Restart the infusion at another site.
- Start supportive treatment (e.g., elevate extremity or apply heat to the site [INS, 2016a]). **Rationale:** *Warmth promotes comfort and vasodilation, facilitating absorption of the fluid from interstitial tissues*.
- If the infiltration involves a **vesicant**, a medication or fluid that causes blisters, severe tissue injury, or necrosis if it escapes from the vein (Mattox, 2017, p. e2), it is called **extravasation** and other measures are indicated. The extravasation of a vesicant drug should be considered an emergency. Usually, vesicants are administered only through CVADs and by specially certified nurses. Most nurses relate vesicants to chemotherapy medications, such as paclitaxel; however, there are a number of non-chemotherapeutic medications (e.g., vancomycin, dopamine, diazepam, phenytoin).
- For an extravasation:
  a. Stop the infusion immediately.
  b. For a short peripheral catheter, disconnect the tubing from the catheter hub and attach a 3- or 5-mL syringe. Aspirate any fluid remaining in the hub and catheter. Do *not* flush the catheter.
  c. Remove the catheter. Use a dry gauze pad to control bleeding.
  d. Apply a new dry dressing. Do not apply excessive pressure to the area. **Rationale:** *Applying pressure will disperse fluid farther into surrounding tissue* (Gorski, 2018, p. 446).
  e. For a CVAD, do not remove the catheter. Clamp and cap the catheter hub. Follow agency procedure for flushing when extravasation is suspected.
  f. Assess motion, sensation, and capillary refill distal to the injury. Measure the circumference of the extremity and compare it with the opposite extremity. Using a skin marker, outline the area with visible signs of extravasation to assess for changes.
  g. Notify the primary care provider.
  h. Photograph the site if that is agency policy.
  i. The affected arm should be elevated and, depending on the drug, heat or cold therapy should be implemented.
  j. Pharmacologic treatment may be instituted depending on the type of vesicant that has caused the damage. Two such medications to lessen tissue injury are phentolamine for extravasation of vasopressors and hyaluronidase, which can be used in extravasation of some hyperosmolar solutions (e.g., calcium chloride), radiographic contrast media, and plant alkaloids (e.g., vincristine) (Gorski, 2018, p. 446). The best results occur when administered immediately after an extravasation (INS, 2016a, p. S100).

8. Inspect the insertion site for phlebitis (inflammation of a vein).
- Inspect and palpate the site at least every 8 hours. Phlebitis can occur as a result of injury to a vein, for example, because of mechanical trauma or chemical irritation. Chemical injury to a vein can occur from IV electrolytes (especially potassium and magnesium) and medications. The clinical signs can include redness, warmth, swelling at the IV site, burning pain along the course of a vein, tenderness, palpable venous cord, and purulent drainage.
- If phlebitis is detected, discontinue the infusion, and apply warm or cold compresses to the venipuncture site. Do not use this injured vein for further infusions.

9. Inspect the IV site for bleeding.
- Oozing or bleeding into the surrounding tissues can occur while the infusion is freely flowing, but is more likely to occur after the catheter has been removed from the vein.
- Observation of the vascular access site is extremely important for clients who bleed readily, such as those receiving anticoagulants.

Monitoring an Intravenous Infusion—*continued*

SKILL 51.2

10. Teach the client ways to maintain the infusion system, for example:
- Inform of any limitations on movement or mobility.
- Explain alarms if an electronic control device is used.
- Instruct to notify a nurse if:
  a. The flow rate suddenly changes or the solution stops dripping.
  b. The solution container is nearly empty.
  c. There is blood in the IV tubing.
  d. Discomfort or swelling is experienced at the IV site.
- Inform that the nurse will be checking the venipuncture site.

11. Document relevant information (often on a specified form).
- Record the status of the IV insertion site and any adverse responses of the client.
- Document the client's IV fluid intake at least every 8 hours according to agency policy. Include the date and time; amount and type of solution used; container number; flow rate; and the client's general response. In most agencies, the amount remaining in each IV container is also recorded at the end of the shift.

EVALUATION
- Perform follow-up based on findings or outcomes that deviated from expected or normal for the client. Consider urinary output compared to intake, tissue turgor, specific gravity of urine, vital signs, and lung sounds compared to baseline data.
- Regularly check the client for intended and adverse effects of the infusion. Report significant deviations from normal to the primary care provider.

Changing Intravenous Containers and Tubing

IV solution containers are changed when only a small amount of fluid remains in the neck of the container and fluid still remains in the drip chamber. However, all IV bags should be changed every 24 hours, regardless of how much solution remains, to minimize the risk of contamination. Change primary administration sets and secondary tubing that remains continuously attached to them "no more frequently than every 96 hours" (INS, 2016a, p. S84). Change intermittent infusion sets without a primary infusion every 24 hours or whenever their sterility is in question (INS, 2016a). Add-on devices (e.g., extension sets, filters, stopcocks) should be changed at the same time the administration set is changed. The INS *Infusion Therapy Standards* (2016a) state to "perform dressing changes on short peripheral catheters if the dressing becomes damp, loosened, or visibly soiled and at least every 5 to 7 days" (p. S82). Skill 51.3 provides guidelines for changing an IV solution container and tubing.

Changing an Intravenous Container and Tubing

SKILL 51.3

PURPOSES
- To maintain the flow of required fluids
- To maintain sterility of the IV system and decrease the incidence of phlebitis and infection
- To maintain patency of the IV tubing

ASSESSMENT

Assess
- Presence of fluid infiltration, leakage, bleeding, or phlebitis at IV site
- Allergy to tape or iodine
- Infusion rate and amount absorbed
- Blockages in IV system
- Appearance of the dressing for integrity, moisture, and need for change

PLANNING

Review primary care provider's orders for changes in fluid administration.

Assignment

This procedure includes assessment of the IV site and should be completed by a registered nurse. In many states, licensed vocational nurses with IV certification may complete the procedure.

Equipment
- Container with the correct kind and amount of sterile solution
- Administration set, including sterile tubing and drip chamber

IMPLEMENTATION

Preparation
- Obtain the correct solution container.
- Read the label of the new container.
- Verify that you have the correct solution, correct client, correct additives (if any), and correct dose (number of bags or total volume ordered).

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how to participate.

2. Perform hand hygiene and observe other appropriate infection prevention procedures.

Continued on page 1390

SKILL 51.3

Changing an Intravenous Container and Tubing—*continued*

3. Set up the IV equipment with the new container and label. See Skill 51.1, steps 1 to 9.
   - Label the tubing as shown in Figure 9 in Skill 51.1.
4. Assess the IV site.
   - Inspect the IV site for the presence of infiltration or inflammation. **Rationale:** *Inflammation or infiltration necessitates removal of the IV catheter to avoid further trauma to the tissues*.
   - Go to step 5 or discontinue and relocate the IV site if indicated. See Skills 51.1 and 51.4.
5. Disconnect the used tubing or remove the cap on an intermittent infusion device (i.e., needleless connector).
   - Apply clean gloves.
   - Place a sterile swab under the hub of the catheter. **Rationale:** *This absorbs any leakage that might occur when the tubing is disconnected*.
   - Clamp the tubing. With the fourth or fifth finger of the nondominant hand, apply pressure to the vein above the end of the catheter. **Rationale:** *This helps prevent blood from coming out of the needle during the change of tubing*.
   - Holding the hub of the catheter with the thumb and index finger of the nondominant hand, remove the tubing or cap with the dominant hand, using a twisting and pulling motion. **Rationale:** *Holding the catheter firmly but gently maintains its position in the vein*.
   - Remove the used IV tubing.
   - Place the end of the used tubing in the basin or other receptacle.
6. Connect the new tubing or cap and reestablish the infusion.
   - Continue to hold the catheter and grasp the new tubing with the dominant hand.
   - Remove the protective tubing cap and, maintaining sterility, insert the tubing end securely into the needle hub. Twist it to secure it.
   - Open the clamp to start the solution flowing.
7. Secure IV tubing with additional tape as required.
8. Regulate the rate of flow of the solution according to the order on the chart.
9. Document all relevant information.
   - Record the change of the solution container and tubing in the appropriate place on the client's chart. Also record the fluid intake according to agency practice. Record the number of the container if the containers are numbered at the agency. Also record your assessments.

EVALUATION

Evaluate the following:

- Status of IV site
- Patency of IV system
- Accuracy of flow

When an IV infusion is no longer necessary to maintain the client's fluid intake or to provide a route for medication administration, the infusion is either discontinued and the catheter removed or the catheter is left in place and converted to a saline lock. Guidelines for discontinuing an IV infusion or converting the catheter to a lock are outlined in Skills 51.4 and 51.5, respectively.

SKILL 51.4

Discontinuing an Intravenous Infusion and Removing a Short Peripheral Catheter

PURPOSE

- To discontinue an IV infusion when the therapy is complete or when the IV site needs to be changed

ASSESSMENT

Assess

- Appearance of the venipuncture site
- Any bleeding from the infusion site
- Amount of fluid infused
- Appearance of short peripheral catheter

PLANNING

Review the client record regarding the primary care provider's orders. Note if there were any previous infusions and if there were any complications and how they were managed.

ASSIGNMENT

In some states and agencies, removal of a peripheral IV catheter may be assigned to AP. In others, removal of IV infusions or devices is not assigned to AP. In any case, the nurse must ensure that the AP knows what complications or adverse signs following removal should be reported to the nurse.

In many states, a licensed practical nurse or licensed vocational nurse with special IV therapy training may discontinue IV infusions. Check the state's nurse practice act.

Equipment

- Clean gloves
- Linen-saver pad
- Small sterile dressing and tape

Discontinuing an Intravenous Infusion—*continued*

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how to participate. Explain the reason for discontinuing the IV and that the procedure should cause no discomfort other than that associated with removing the tape.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Assist the client to a comfortable position, either sitting or lying. Expose the IV site but provide for client privacy. Place a linen-saver pad under the extremity that has the IV.
4. Prepare the equipment.
   - Clamp the infusion tubing. **Rationale:** *Clamping the tubing prevents the fluid from flowing out of the needle onto the client or bed*.
   - Apply clean gloves.
   - Remove the dressing, stabilization device, and tape at the venipuncture site while holding the needle firmly and applying countertraction to the skin. ❶ **Rationale:** *Movement of the catheter can injure the vein and cause discomfort to the client. Countertraction prevents pulling the skin and causing discomfort*. Use appropriate solution (e.g., alcohol) as indicated to loosen the dressing and securement device adhesive.
   - Assess the vascular access site. **Rationale:** *Assess for signs of infection or phlebitis*.
   - Apply the sterile gauze above the vascular access site with the nondominant hand. Only touch the upper portion of the gauze pad and maintain sterility of the lower portion that is in contact with the venipuncture site.
5. Withdraw the catheter from the vein with the dominant hand.
   - Withdraw the catheter by pulling it out along the line of the vein using gentle, even pressure. **Rationale:** *Pulling it out in line with the vein avoids injury to the vein*. Do not press down on the sterile gauze pad while removing the catheter. ❷
   - Immediately apply firm pressure to the site, using sterile gauze, for a minimum of 30 seconds or until hemostasis is achieved. **Rationale:** *Pressure helps stop the bleeding and prevents hematoma formation*.
   - Hold the client's arm above heart level if any bleeding persists. **Rationale:** *Raising the limb decreases blood flow to the area*.
   - Teach the client to inform the nurse if the site begins to bleed at any time or the client notes any other abnormalities in the area.

❶ Remove the dressing, stabilization device, and tape while holding the IV catheter firmly.

❷ Withdraw the IV catheter from the vein. Do not apply pressure on the sterile gauze pad until the catheter is completely removed.

6. Examine the catheter removed from the client.
   - Check the catheter to make sure it is intact. **Rationale:** *If a piece of tubing remains in the client's vein it could move centrally (toward the heart or lungs)*.
   - Report a broken catheter to the nurse in charge or the primary care provider immediately.
   - If a broken piece can be palpated, apply a tourniquet above the insertion site. **Rationale:** *Application of a tourniquet decreases the possibility of the piece moving until a primary care provider is notified*.
7. Cover the venipuncture site.
   - Apply new sterile dressing to the site with tape. ❸ **Rationale:** *The dressing continues the pressure and covers the open area in the skin, preventing infection*.
   - Discard used supplies appropriately.
   - Remove and discard gloves.
   - Perform hand hygiene.
8. Read the amount remaining in the IV solution container.
9. Apply a black-out label (❹*A*) over the existing IV solution label prior to discarding the IV solution into a biohazard container (❹*B*). **Rationale:** *The existing IV label contains client information. The black-out label conceals client information and ensures client confidentiality*. These labels are called IV HIPAA-compliant labels.
10. Document all relevant information.
    - Record the amount of fluid infused on the intake and output record and in the record, according to agency policy. Include the container number, type of solution used, time of discontinuing the infusion, and the client's response.

❸ Apply new sterile dressing to the site with tape.

SKILL 51.4

Discontinuing an Intravenous Infusion—*continued*

A

B

4 *A*, An IV black-out label; *B*, discarding an IV bag into a biohazard container after applying a black-out label to ensure client confidentiality.

EVALUATION

- Perform follow-up based on findings or outcomes that deviated from expected or normal for the client. Relate findings to previous data if available.
- Report significant deviations from normal to the primary care provider.

SKILL 51.5

Changing a Short Peripheral Catheter to an Intermittent Infusion Device

PURPOSE

- To permit IV administration of medications or fluids on an intermittent basis

ASSESSMENT

Assess

- Patency of the IV catheter
- Appearance of the site (evidence of inflammation or infiltration)

PLANNING

Review the primary care provider's order.

- A specific order may be written to insert or convert peripheral vascular access to a saline lock. The order also may be implied; for example, IV fluids are to be discontinued but the client has orders for an IV antibiotic every 6 hours or is receiving analgesics intravenously.
- From the primary care provider's order, determine the type and sequence of intermittent infusions.
- Review the client record regarding previous infusions and use of infusion devices. Note any complications and how they were managed.

Assignment

Due to the need for sterile technique and technical complexity, this procedure is not assigned to AP. AP may care for clients with such devices, and the nurse must ensure that the AP knows what complications or adverse signs should be reported to the nurse.

In many states, a licensed practical nurse or licensed vocational nurse with special IV therapy training may manage intermittent infusion devices. Check the state's nurse practice act.

Equipment

- Needleless connector
- Extension tubing (optional)
- Clean gloves
- TSM dressing
- Sterile 2×2 or 4×4 gauze
- Sterile saline for injection (without preservative) in a prefilled syringe
- Isopropyl alcohol wipes
- Tape
- Clean emesis basin

Changing a Short Peripheral Catheter to an Intermittent Infusion Device—*continued*

SKILL 51.5

IMPLEMENTATION

Preparation

- Obtain the needed equipment and take to the client's bedside.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how to participate. Explain the reason for the intermittent infusion device and that changing an IV to a saline lock should cause no discomfort other than that associated with removing tape from the IV tubing.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Assist the client to a comfortable position, either sitting or lying. Expose the IV site but provide for client privacy.
4. Assess the IV site and determine the patency of the catheter (see Skill 51.2). If the catheter is not fully patent or there is evidence of phlebitis or infiltration, discontinue the catheter and establish a new vascular access site.
   - Expose the IV catheter hub and loosen any tape or dressing that is holding the IV tubing in place or that will interfere with insertion of the needleless connector with extension tubing into the catheter.
   - Clamp the IV tubing to stop the flow of IV fluid.
   - Open the gauze pad and place it under the IV catheter hub. **Rationale:** *This absorbs any leakage that might occur when the tubing is disconnected*.
   - Open the alcohol wipe and needleless connector, leaving the needleless connector in its sterile package.
   - Consider use of an extension tubing between the peripheral catheter and needleless connector. **Rationale:** *This reduces catheter manipulation, which can cause phlebitis*. Prime the extension tubing.
5. Remove the IV tubing and insert the needleless connector and extension tubing into the short peripheral catheter.
   - Apply clean gloves.
   - Stabilize the IV catheter with your nondominant hand and use the little finger to place slight pressure on the vein above the end of the catheter. Twist the IV tubing connection to loosen it from the IV catheter and remove it, placing the end of the tubing in a clean emesis basin.
   - Pick up the needleless connector from its package and remove the protective sleeve from the male adapter maintaining its sterility. Insert the connector into the IV catheter or extension tubing, twisting it to engage the Luer-Lok. Do not allow the male luer of the extension set to touch the skin.
6. Instill saline per agency policy. **Rationale:** *Saline is used to maintain patency of the IV catheter when fluids are not infusing through the catheter*. The intermittent lock will need to be flushed with a prescribed solution after each intermittent infusion or at least every 24 hours if not in use, according to agency policy (Gorski, 2018). The INS recommends the smallest volume for flushing with most organizations using 3 mL. Nurses may use different methods of flushing. Some recommend flushing the lock by injecting saline using the push–pause method (a rapid succession of push–pause–push–pause movements exerted on the plunger of the syringe barrel) with the rationale that this creates a turbulence within the catheter lumen that causes a swirling effect to remove any debris (e.g., blood or medication) attached to the catheter lumen. However, no research supports this method of flushing. There are differences of opinion and practice regarding this type of flushing versus a smooth injection of the flush solution. Research is needed to provide evidence of which is the most effective (Gorski, 2018, p. 303).
7. Cover the site with a TSM dressing. **Rationale:** *The TSM dressing provides protection from infection, allows for ease of assessment of the venipuncture site, and also promotes comfort, preventing the plug from catching on clothing or bedding*.
8. Remove and discard gloves.
   - Perform hand hygiene.
9. Teach the client how to maintain the lock.
   - Notify the nurse or primary care provider if the needleless connector or IV catheter comes out; if the site becomes red, inflamed, or painful; or if any drainage or bleeding occurs at the site.
10. Document all relevant information.
    - Record the date and time when the infusion device was converted, the status of the IV insertion site, and any adverse responses of the client.

EVALUATION

- Perform follow-up based on findings or outcomes that deviated from expected or normal for the client. Relate findings to previous data if available.
- Examine the IV site at regular intervals. Note patency and ease of flushing.
- Report significant deviations from normal to the primary care provider.

Complications of Infusion Therapy

Local complications of infusion therapy occur as adverse reactions or trauma to the venipuncture site. Correct venipuncture technique is a primary factor in prevention along with frequent assessments and monitoring of the venipuncture site. Common local complications include infiltration, extravasation, and phlebitis.

Infiltration can be caused by puncture of the vein during venipuncture, dislodgement of the catheter, or a poorly secured infusion device (Gorski, 2018).

Extravasation is similar to infiltration with the difference between the two being the solution. That is, extravasation is the unintended administration of *vesicant* drugs or fluids into the subcutaneous tissue. Five measures can help prevent infiltration and extravasation. The first measure is the selection of the venipuncture site. Areas of joint flexion such as the hand, wrist, and antecubital fossa should be avoided. The gauge of the catheter should be the smallest that can deliver the prescribed therapy in an appropriate size vein. Knowing the osmolality and pH of medications and fluids is also important. For example, hypertonic fluids and medications should not be infused through a peripheral vein. Using a manufactured catheter stabilization device to prevent unnecessary movement of

the catheter in the vein is the fourth measure. Finally, the last measure is assessing patency of the catheter and vein frequently.

Phlebitis is an inflammation of the vein of which there are three types. *Mechanical phlebitis* can be caused by too large of a catheter in a small vein or catheter movement causing irritation of the vein. *Chemical phlebitis* occurs when a vein becomes inflamed by irritating or vesicant solutions or medications. *Bacterial phlebitis* is inflammation of the vein and a bacterial infection, which can be caused by poor aseptic technique during insertion of the IV catheter or breaks in the integrity of the IV equipment. See Box 51.7 for common signs and symptoms of infiltration, extravasation, and phlebitis.

It is important for the nurse to regularly assess all clients with an IV access for signs of phlebitis. One of the INS *Standards* directs nurses to document symptoms of phlebitis using a standardized scale (INS, 2016a). While recent evidence recommends a need for a phlebitis scale that has strong measurement properties for use in clinical practice, there are two commonly used assessment scales that are also recommended by the INS: the INS Phlebitis Scale and the Visual Infusion Phlebitis (VIP) Scale. The INS Phlebitis Scale progresses from Grade 0 (no symptoms) to Grade 4 (includes all symptoms: pain, erythema, streak formation, palpable venous cord, purulent drainage). The VIP Scale progresses from Score 0 (no symptoms) to Score 5 (all symptoms) (INS, 2016a, p. S96)

Prevention strategies for phlebitis include practicing good hand hygiene, assessing the length of time needed for the infusion therapy, and considering alternatives (e.g., midline catheter or PICC) for long-term therapy, choosing the smallest catheter, stabilizing the catheter, infusing solutions at the prescribed rate, avoiding insertion of a peripheral IV catheter in an area of flexion, and assessing the IV site at least every 4 hours (Gorski, 2018, p. 443).

BOX 51.7 Signs and Symptoms of Common Local Complications of Infusion Therapy

INFILTRATION
- Coolness of skin around site
- Skin blanching, tautness (i.e., client states it feels "tight")
- Edema at, above, or below the insertion site
- Leakage at insertion site
- Absence of or "pinkish" blood return
- Difference in size of opposite hand or arm

EXTRAVASATION
Same as infiltration and can also include:
- Burning, stinging pain
- Redness followed by blistering, tissue necrosis, and ulceration

PHLEBITIS
- Redness at the site
- Skin warm
- Swelling
- Palpable cord along the vein
- Increase in temperature

From "Complications of Peripheral Venous Access Devices: Prevention, Detection, and Recovery Strategies," by E. Mattox, 2017, *Critical Care Nurse, 37*(2), pp. e1–e14; *Phillips's Manual of I.V. Therapeutics* (7th ed.), by L. A. Gorski, 2018, Philadelphia, PA: F.A. Davis; and *Infusion Therapy Standards of Practice* (5th ed.), by Infusion Nurses Society, 2016a, Norwood, MA: Author.

Blood Transfusions

IV fluids can be effective in restoring intravascular (blood) volume; however, they do not affect the oxygen-carrying capacity of the blood. When red or white blood cells, platelets, or blood proteins are lost because of hemorrhage or disease, it may be necessary to replace these components to restore the blood's ability to transport oxygen and carbon dioxide, clot, fight infection, and keep extracellular fluid within the intravascular compartment. A blood transfusion is the introduction of whole blood or blood components into venous circulation.

Blood Groups

Human blood is commonly classified into four main groups: A, B, AB, and O. The surface of an individual's RBCs contains a number of proteins known as **antigens** that are unique for each individual. Many blood antigens have been identified, but the A, B, and Rh antigens are the most important in determining blood group or type. Because antigens promote agglutination or clumping of blood cells, they are also known as **agglutinogens**. The A antigen is present on the RBCs of individuals with blood group A, the B antigen is present on the RBCs of individuals with blood group B, and A and B antigens are both present on the RBCs in individuals with group AB blood. Neither antigen is present on the RBCs of individuals with group O blood.

Preformed **antibodies** to RBC antigens are present in the plasma; these antibodies are often called **agglutinins**. Individuals with blood group A have B antibodies (agglutinins); A antibodies are present in individuals with blood group B; and individuals with blood group O have antibodies to both A and B antigens. Individuals with group AB blood do not have antibodies to either A or B antigens (Table 51.12). These naturally occurring antibodies are responsible for the rapid and severe reaction that occurs when ABO-incompatible blood is administered (Gorski, 2018).

Rhesus (Rh) Factor

The Rh factor antigen is present on the RBCs of approximately 85% of the people in the United States. Blood

TABLE 51.12 The Blood Groups with Their Constituent Agglutinogens and Agglutinins

Blood Types	RBC Antigens (Agglutinogens)	Plasma Antibodies (Agglutinins)
A	A	B
B	B	A
AB	A and B	—
O	—	A and B

that contains the Rh factor is known as Rh positive (Rh^+); blood that does not contain the Rh factor is known as Rh negative (Rh^-). In contrast to the ABO blood groups, Rh^- blood does not naturally contain Rh antibodies. However, after exposure to blood containing Rh factor (e.g., an Rh^- mother carrying a fetus with Rh^+ blood, or transfusion of Rh^+ blood into a client who is Rh^-), Rh antibodies develop. Subsequent exposure to Rh^+ blood places the client at risk for an antigen–antibody reaction and hemolysis of RBCs.

Blood Typing and Crossmatching

To avoid transfusing incompatible RBCs, blood from the donor and from the recipient is tested for compatibility. This is referred to as a *type and crossmatch*. Blood typing is done to determine the ABO blood group and Rh factor status. This test is also performed on pregnant women and neonates to assess for incompatibility between their blood types (particularly Rh factor incompatibilities).

Because blood typing only determines the presence of the ABO and Rh antigens, crossmatching is also necessary prior to transfusion to identify possible interactions of minor antigens with their corresponding antibodies. RBCs from the donor blood are mixed with serum from the recipient; a reagent (Coombs' serum) is added, and the mixture is examined for visible agglutination. If no antibodies to the donated RBCs are present in the recipient's serum, agglutination does not occur and the risk of a transfusion reaction is small.

QSEN Patient-Centered Care: Blood and Blood Products

Jehovah's Witness is a Christian religion that believes that taking blood into the body causes loss of eternal life; thus the church decided that members who accepted blood would be shunned by the congregation and denied the church's sacraments (called "disfellowshipped"). In 2000, this policy on blood transfusions was revised to allow the acceptance of blood products based on personal decision and conscience. Based on this change in doctrine, members of this religion have medical confidentiality from the church. However, if there is a breach in the medical confidentiality, the member is "disfellowshipped" by the church. Providing culturally responsive care to this population means it is important for the healthcare provider to interview these clients privately and allow them to make informed decisions about their personal choice to accept or deny blood products. Their decisions should be private and not discussed in front of friends or family members (Campbell, Machan, & Fisher, 2016).

Selection of Blood Donors

Screening of blood donors is rigorous. Criteria have been established to protect the donor from possible ill effects of donation and to protect the recipient from exposure to diseases transmitted through the blood. Blood donors are unpaid volunteers. Potential donors are eliminated by a history of hepatitis B or C, HIV infection (or risk factors for HIV infection), heart disease, most cancers, severe asthma, bleeding disorders, or seizures. Donation may be deferred for individuals who have malaria, have been exposed to malaria or hepatitis, are anemic, have high or low BP, have low body weight, or who are pregnant, have had recent surgery, or take certain medications. Receiving tattoos or piercings in unlicensed facilities results in a 12-month deferral period by the Red Cross (MacIntyre, 2017, p. 46).

Blood and Blood Products for Transfusion

Most clients do not require transfusion of whole blood. It is much more common for clients to receive a transfusion of a particular blood component specific to their individual needs. Table 51.13 lists some of the common blood products that may be transfused.

TABLE 51.13 Blood Products for Transfusion

Product	Use
Whole blood	Not commonly used except for extreme cases of acute hemorrhage. Replaces blood volume and all blood products: RBCs, plasma, plasma proteins, fresh platelets, and other clotting factors.
Packed red blood cells (PRBCs)	Used to increase the oxygen-carrying capacity of blood in anemias, surgery, and disorders with slow bleeding. One unit of PRBCs has the same amount of oxygen-carrying RBCs as a unit of whole blood. One unit raises hematocrit by approximately 2% to 3%.
Autologous RBCs	Used for blood replacement following planned elective surgery. Client donates blood for autologous transfusion 4–5 weeks prior to surgery.
Platelets	Replaces platelets in clients with bleeding disorders or platelet deficiency. Fresh platelets are most effective. Each unit should increase the average adult client's platelet count by about 5000 platelets per microliter.
Fresh frozen plasma	Provides clotting factors. Does not need to be typed and crossmatched (contains no RBCs).
Albumin and plasma protein fraction	Blood volume expander; provides plasma proteins.
Clotting factors and cryoprecipitate	Used for clients with clotting factor deficiencies. Each provides different factors involved in the clotting pathway; cryoprecipitate also contains fibrinogen.

Transfusion Reactions

Transfusion of ABO- or Rh- incompatible blood can result in an **acute hemolytic transfusion reaction (AHTR)**, which causes destruction of the transfused RBCs and subsequent risk of kidney damage or failure. Other forms of acute transfusion reactions may also occur, including febrile or allergic reactions, transfusion-associated circulatory overload (TACO) , and transfusion-related acute lung injury (TRALI). Because the risk of an adverse reaction is high when blood is transfused, clients must be frequently and carefully assessed before and during transfusion. Many reactions become evident within 5 to 15 minutes of initiating the transfusion, but reactions can develop any time during a transfusion; for this reason, clients are most closely monitored during the initial period of the transfusion. Stop the transfusion immediately if signs of a reaction develop. Keep the line open with normal saline. Do not use the saline attached to the Y-set tubing because the filter contains blood and you do not want to give the client who is experiencing an acute transfusion reaction another drop of blood. Instead, use new IV tubing. Disconnect the infusion tubing from the hub of the IV catheter and replace with the new IV tubing. Do not piggyback the new tubing into the access port of the transfusion tubing, because it is possible that some of the blood product could be administered to the client. Hydrate the client with normal saline and notify the primary care provider. Continue to monitor vital signs (Gorski, 2018). Possible transfusion reactions, their clinical signs and symptoms, and nursing implications are listed in Table 51.14.

TABLE 51.14 Transfusion Reactions

Reaction: Cause	Clinical Signs	Nursing Intervention*
Acute hemolytic transfusion reaction (AHTR): incompatibility between client's blood and donor's blood	Fever or chills, flank pain, and reddish or brown urine, tachycardia, hypotension	**1.** Discontinue the transfusion immediately. *Note*: When the transfusion is discontinued, the blood tubing must be removed as well. Use *new* tubing for the normal saline infusion. **2.** Maintain vascular access with normal saline, or according to agency protocol. **3.** Notify the primary care provider immediately. **4.** Monitor vital signs. **5.** Monitor fluid intake and output. **6.** Send the remaining blood, bag, filter, tubing, a sample of the client's blood, and a urine sample to the laboratory.
Nonhemolytic febrile reaction: sensitivity of the client's blood to white blood cells, platelets, or plasma proteins; does not cause hemolysis	Fever; chills; warm, flushed skin; headache; anxiety; nausea, vomiting	**1.** Discontinue the transfusion immediately. **2.** Keep the vein open with a normal saline infusion. **3.** Notify the primary care provider. **4.** Give antipyretics as ordered.
Allergic reaction (mild): sensitivity to infused plasma proteins	Flushing, urticaria, with or without itching	**1.** Stop the transfusion immediately. Keep vein open with normal saline. **2.** Notify the primary care provider. **3.** Administer medication (antihistamines, steroids) as ordered.
Allergic reaction (severe): antibody–antigen reaction	Dyspnea, stridor, decreased oxygen saturation, hypotension, shock	**1.** Stop the transfusion immediately. **2.** Keep the vein open with a normal saline solution. **3.** Notify the primary care provider immediately. **4.** Monitor vital signs. Administer cardiopulmonary resuscitation if needed. **5.** Administer medications and/or oxygen as ordered.
Transfusion-associated circulatory overload (TACO): blood administered faster than the circulation can accommodate or client has underlying cardiovascular or renal dysfunction	Dyspnea, orthopnea, crackles (rales), distended neck veins, tachycardia, hypertension	**1.** Stop the transfusion immediately. **2.** Place the client upright. **3.** Notify the primary care provider. **4.** Administer diuretics and oxygen as ordered.
Transfusion-related acute lung injury (TRALI); occurs in response to infused donor leukocyte antibodies	Acute respiratory distress, hypotension, hypoxemia, fever, chills	**1.** Stop the transfusion. **2.** Keep the vein open with a normal saline infusion. **3.** Notify the primary care provider. **4.** Oxygen therapy with or without mechanical ventilation **5.** Hypotension often corrected by fluid resuscitation. Vasopressor therapy may be needed. **6.** Send the remaining blood and tubing to the laboratory.

* Nurses should follow the agency's protocol regarding interventions. These may vary among agencies.

From "A Review of Current Practice in Transfusion Therapy" by M. Carman, J. Uhlenbrock, & S. McClintock, 2018, *American Journal of Nursing, 118*(5), pp. 36–44; "Early Identification of Acute Hemolytic Transfusion Reactions: Realistic Implications for Best Practice in Patient Monitoring" by J. B. Menendez & B. Edwards, 2016, *MEDSURG Nursing, 25*(2), pp. 88–90; and *Phillips's Manual of I.V. Therapeutics* (7th ed.), by L. A. Gorski, 2018, Philadelphia, PA: F.A. Davis.

The hospital must have a protocol relating to transfusion reactions. Common measures include:

- Notify the blood bank.
- Examine the label on the blood container to check for errors in identifying the client, blood, or blood component.
- Obtain laboratory specimens (e.g., blood work, urine sample).
- Send blood container (whether or not it contains any blood), attached infusion set, and IV solution to the blood bank.

Administering Blood

Special precautions are necessary when administering blood. When a transfusion is ordered, the nurse or other personnel obtain blood in plastic bags from the blood bank just before starting the transfusion. One unit of whole blood is 500 mL; a unit of packed red blood cells (PRBCs) is 200 to 250 mL. Do not store the blood in the refrigerator on the nursing unit; lack of temperature control may damage the blood. Once blood or a blood product is removed from the blood bank refrigerator, it must be administered within a limited amount of time (e.g., PRBCs should not hang for more than 4 hours after being removed from the blood bank refrigerator). Follow agency policies for verifying that the unit is correct for the client. The U.S. Food and Drug Administration ([FDA], 2018) requires blood products to have bar codes to allow for scanning and machine-readable information on blood and blood component container labels to help reduce medication errors and increase client safety.

Traditionally, blood has usually been administered through an #18- to #20-gauge IV needle or catheter with the belief being that using smaller needles may slow the infusion and damage blood cells (hemolysis). However, studies have shown that blood infusions through smaller gauge catheters can be completed within 4 hours without hemolysis. Current practice guidelines established by the INS recommend that a #20- to #24-gauge short peripheral catheter is acceptable for transfusion of cellular blood components in adults (INS, 2016b, p. 225). When rapid transfusion is required a #14 to #18-gauge is recommended (INS, 2016a, p. S135). Blood administration sets (Y-sets) are used to keep the vein open while starting the transfusion and to flush the line with normal saline before the blood enters the tubing (Figure 51.32 ■). The infusion tubing has a filter inside the drip chamber. A transfusion should be completed within 4 hours of initiation. The maximum time for use of a blood filter is 4 hours (Gorski, 2018). The INS (2016a) states: "Administer blood or blood components with 0.9% sodium chloride. No other solutions or medications should be added to or infused through the same administration set with blood or blood components unless they have been approved by the FDA for this use" (p. S136). If an additional unit needs to be transfused, follow agency guidelines. A new blood administration set is to be used with each component, or

Safety Alert! SAFETY

2019 The Joint Commission National Patient Safety Goals

Goal 1: Improve the accuracy of patient identification.
Goal 01.03.01: Eliminate transfusion errors related to patient misidentification.

- Before initiating a blood or blood component transfusion:
  - Match the blood or blood component to the order.
  - Match the patient to the blood or blood component.
  - Use a two-person verification process or a one-person verification process accompanied by automated identification technology, such as bar coding.

© Joint Commission Resources: Comprehensive Accreditation Manual for Hospitals, National Patient Safety Goals. Oakbrook Terrace, IL: Joint Commission on Accreditation of Healthcare Organizations, 2019, NPSG-1-23. Reprinted with permission.

Figure 51.32 ■ Schematic of a Y-set for blood administration.

if more than 1 unit can be infused in 4 hours, the transfusion set can be used for a 4-hour period (Gorski, 2018, p. 580). New IV tubing is used for administering other IV fluids following a transfusion.

To initiate, maintain, and terminate a blood transfusion, see Skill 51.6.

Clinical Alert!

Normal saline must always be used when giving a blood transfusion. If the client has an infusion of any other IV solution, stop that infusion and flush the line with saline prior to initiating the transfusion, or establish IV access through an additional site. Solutions other than saline can cause damage to the blood components.

SKILL 51.6

Initiating, Maintaining, and Terminating a Blood Transfusion Using a Y-Set

PURPOSES

- To restore blood volume after severe hemorrhage
- To restore the oxygen-carrying capacity of the blood
- To provide plasma factors, such as antihemophilic factor (AHF) or factor VIII, or platelet concentrates, which prevent or treat bleeding

ASSESSMENT

Assess

- Vital signs; oxygen saturation is often included
- Physical examination including fluid balance and heart and lung sounds as manifestations of hypo- or hypervolemia
- Status of infusion site and patency of vascular access device
- Blood test results such as hemoglobin value or platelet count
- Any unusual symptoms

PLANNING

- Review the client record regarding previous transfusions. Note any complications and how they were managed (e.g., allergies or previous adverse reactions to blood).
- Confirm the primary care provider's order for the number and type of units and the desired speed of infusion.
- In some agencies, written consent for transfusion is required. Check policy and obtain as indicated.
- Know the purpose of the transfusion.
- Plan to begin the transfusion as soon as the component is ready. Typing and crossmatching can take several hours.
- Note any premedication ordered by the primary care provider (e.g., acetaminophen or diphenhydramine). Schedule their administration (usually 30 minutes prior to the transfusion).

Assignment

Due to the need for sterile technique and technical complexity, blood transfusion is not assigned to AP. The nurse must ensure that the AP knows what complications or adverse signs can occur and should be reported to the nurse. In some states only registered nurses (RNs) can administer blood or blood products.

Equipment

- Unit of whole blood, PRBCs, or other component
- Blood administration set
- IV pump, if needed (use EIDs that have a labeled indication for blood transfusion)
- 250 mL normal saline for infusion
- IV pole
- Venipuncture set containing a #20- to #24-gauge catheter (if one is not already in place)
- Alcohol swabs
- Tape
- Clean gloves

IMPLEMENTATION

Preparation

- If the client has an IV solution infusing, check whether the IV catheter and solution are appropriate to administer blood. The IV catheter size ranges between #20 and #24 gauge, and the solution *must* be normal saline. Dextrose (which causes lysis of RBCs), Ringer's solution, medications and other additives, and hyperalimentation solutions are incompatible. Refer to step 6 if the infusing solution is not compatible.
- If the client does not have an IV solution infusing, check agency policies. In some agencies an infusion must be running before the blood is obtained from the blood bank. In this case, you will need to perform a venipuncture on a suitable vein (see Skill 51.1) and start an IV infusion of normal saline.
- Obtain assistance of another RN to perform client and blood identification process.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how to participate. Instruct the client to report promptly any sudden chills, nausea, itching, rash, dyspnea, back pain, or other unusual symptoms.
2. Provide for client privacy and prepare the client.
   - Assist the client to a comfortable position, either sitting or lying. Expose the IV site but provide for client privacy.
3. Perform hand hygiene and observe other appropriate infection prevention procedures.
4. Prepare the infusion equipment.
   - Ensure that the blood filter inside the drip chamber is suitable for the blood components to be transfused.

Initiating, Maintaining, and Terminating a Blood Transfusion Using a Y-Set—*continued*

Attach the blood tubing to the blood filter, if necessary. **Rationale:** *Blood filters have a surface area large enough to allow the blood components through easily but are designed to trap clots*.
- Apply gloves.
- Close all the clamps on the Y-set: the main flow rate clamp and both Y-line clamps.
- Insert the piercing pin (spike) into the saline solution.
- Hang the container on the IV pole about 1 m (39 in.) above the venipuncture site.

5. Prime the tubing.
- Open the upper clamp on the normal saline tubing, and squeeze the drip chamber until it covers the filter and one-third of the drip chamber above the filter.
- Tap the filter chamber to expel any residual air in the filter.
- Open the main flow rate clamp, and prime the tubing with saline.
- Close both clamps.

6. Start the saline solution.
- If an IV solution incompatible with blood is infusing, stop the infusion and discard the solution and tubing according to agency policy.
- Attach the blood tubing primed with normal saline to the IV catheter.
- Open the saline and main flow rate clamps and adjust the flow rate. Use only the main flow rate clamp to adjust the rate.
- Allow a small amount of solution to infuse to make sure there are no problems with the flow or with the venipuncture site. **Rationale:** *Infusing normal saline before initiating the transfusion also clears the IV catheter of incompatible solutions or medications*.

7. Obtain the correct blood component for the client.
- Check the primary care provider's order with the requisition.
- Check the requisition form and the blood bag label with a laboratory technician or according to agency policy. Specifically, check the client's name, identification number, blood type (A, B, AB, or O) and Rh group, the blood donor number, and the expiration date of the blood. Observe the blood for abnormal color, RBC clumping, gas bubbles, and extraneous material. Return outdated or abnormal blood to the blood bank.
- With another nurse (most agencies require an RN) and in the presence of the client, verify the following before initiating the transfusion (Gorski, 2018, p. 584; INS, 2016b, p. 229):
  a. *Order:* Check the blood or component against the primary care provider's written order.
  b. *Transfusion consent form:* Ensure the form is completed per facility policy.
  c. *Client identification:* The name and identification number on the client's identification band must be identical to the name and number attached to the unit of blood.
  d. *Unit identification:* The unit identification number on the blood container, the transfusion form, and the tag attached to the unit must agree.
  e. *Blood type:* The ABO group and Rh type on the primary label of the donor unit must agree with those recorded on the transfusion form.
  f. *Expiration:* The expiration date and time of the donor unit should be verified as acceptable.
  g. *Compatibility:* The interpretation of compatibility testing must be recorded on the transfusion form and on the tag attached to the unit.
  h. *Appearance:* There should be no discoloration, foaming, bubbles, cloudiness, clots or clumps, or loss of integrity of the container.

Clinical Alert!

It is safer to have one nurse read the information for verification to the other nurse; this avoids errors that can be made if both nurses look at the tags together.

- If any of the information does not match *exactly*, notify the charge nurse and the blood bank. Do not administer blood until discrepancies are corrected or clarified.
- Sign the appropriate form with the other nurse according to agency policy.
- Make sure that the blood is left at room temperature for no more than 30 minutes before starting the transfusion. Agencies may designate different times at which the blood must be returned to the blood bank if it has not been started. **Rationale:** *As blood components warm, the risk of bacterial growth also increases*. If the start of the transfusion is unexpectedly delayed, return the blood to the blood bank after 30 minutes. Do *not* store blood in the unit refrigerator. **Rationale:** *The temperature of unit refrigerators is not precisely regulated and the blood may be damaged*.

8. Prepare the blood bag.
- Invert the blood bag gently several times to mix the cells with the plasma. **Rationale:** *Rough handling can damage the cells*.
- Expose the port on the blood bag by pulling back the tabs.
- Insert the remaining Y-set spike into the blood bag.
- Suspend the blood bag.

9. Establish the blood transfusion.
- Close the upper clamp below the IV saline solution container.
- Open the upper clamp below the blood bag. The blood will run into the saline-filled drip chamber. If necessary, squeeze the drip chamber to reestablish the liquid level with the drip chamber one-third full. (Tap the filter to expel any residual air within the filter.)
- Readjust the flow rate with the main clamp.
- Remove and discard gloves.
- Perform hand hygiene.

10. Observe the client closely for the first 15 minutes.
- INS (2016b) states to "start the transfusion slowly at approximately 2 mL per minute for the first 15 minutes, and remain near the patient; increase the transfusion rate if there are no signs of a reaction" (p. 230). **Rationale:** *This small amount is enough to produce a severe reaction but small enough that the reaction could be treated successfully*.

Continued on page 1400

SKILL 51.6

Initiating, Maintaining, and Terminating a Blood Transfusion Using a Y-Set—*continued*

- Note adverse reactions, such as chills, nausea, vomiting, skin rash, dyspnea, back pain, or tachycardia. **Rationale:** *The earlier a transfusion reaction occurs, the more severe it tends to be. Promptly identifying such reactions helps to minimize the consequences*.
- Remind the client to call a nurse immediately if any unusual symptoms are felt during the transfusion such as chills, nausea, itching, rash, dyspnea, or back pain.
- If any of these reactions occur, report them to the nurse in charge, and take appropriate nursing action. See Table 51.14 on page 1396.

11. Document relevant data.
- Record starting the blood, including vital signs, type of blood, blood unit number, sequence number (e.g., #1 of three ordered units), site of the venipuncture, size of the catheter, and drip rate.

SAMPLE DOCUMENTATION

1/21/2020 1400 1 unit of PRBCs (#65234) hung to be infused over 3 hours. IV site in (L) forearm with 20 guage angiocath. VS taken (see transfusion record). Informed to contact nurse if begins to experience any discomfort during transfusion. Stated he would use the call light. C. Jones, RN

12. Monitor the client.
- 15 minutes after initiating the transfusion (or according to agency policy), check the vital signs. If there are no signs of a reaction, establish the required flow rate. Most adults can tolerate receiving 1 unit of blood in 1.5 to 2 hours. Do not transfuse a unit of blood for longer than 4 hours.
- Assess the client, including vital signs, per agency policy. If the client has a reaction and the blood is discontinued, send the blood bag and tubing to the laboratory for investigation of the blood.

13. Terminate the transfusion.
- Apply clean gloves.
- If no infusion is to follow, clamp the blood tubing. Check agency protocol to determine if the blood component bag needs to be returned or if the blood bag and tubing can be disposed of in a biohazard container. The IV line can be discontinued or capped with an adapter or a new infusion line and solution container may be added. If another transfusion is to follow, clamp the blood tubing and open the saline infusion arm. Check agency protocol. A new blood administration set is to be used with each component, or if more than 1 unit can be infused in 4 hours, the transfusion set can be used for a 4-hour period (Gorski, 2018, p. 580).
- If the primary IV is to be continued, flush the maintenance line with saline solution. Disconnect the blood tubing system and reestablish the IV infusion using new tubing. Adjust the drip to the desired rate. Often a normal saline or other solution is kept running in case of delayed reaction to the blood.
- Measure vital signs.

14. Follow agency protocol for appropriate disposition of the used supplies.
- Discard the administration set according to agency practice.
- Dispose of blood bags and administration sets.
  a. On the requisition attached to the blood unit, fill in the time the transfusion was completed and the amount transfused.
  b. Attach one copy of the requisition to the client's record and another to the empty blood bag if required by agency policy.
  c. Agency policy generally involves returning the bag to the blood bank for reference in case of subsequent or delayed adverse reaction.
- Remove and discard gloves.
- Perform hand hygiene.

15. Document relevant data.
- Record completion of the transfusion, the amount of blood absorbed, the blood unit number, and the vital signs. If the primary IV infusion was continued, record connecting it. Also record the transfusion on the IV flow sheet and intake and output record.

SAMPLE DOCUMENTATION

4/21/2020 1415 c/o feeling warm, headache, & backache. Skin flushed. T 102.6°F, BP 140/90, P 112, R 28. Approximately 50 mL PRBCs (#65234) infused over past 15 minutes. Infusion stopped. IV tubing changed, NS infusing at 15 mL/hr. Blood & attached tubing sent to blood bank. Dr. Riley notified. Will continue to monitor. C. Jones, RN

EVALUATION

- Perform follow-up based on findings or outcomes that deviated from expected or normal for the client. Compare findings to previous data if available.
- Report significant deviations from normal to the primary care provider.

Evaluating

Using the overall goals identified in the planning stage of maintaining or restoring fluid balance, maintaining or restoring pulmonary ventilation and oxygenation, maintaining or restoring normal balance of electrolytes, and preventing associated risks of fluid, electrolyte, and acid–base imbalances, the nurse collects data to evaluate the effectiveness of interventions.

If desired outcomes are not achieved, the nurse, client, and support person if appropriate need to explore the reasons before modifying the care plan. For example, if the outcome "Urine output is greater than 1300 mL per day and within 500 mL of intake" is not achieved, questions to be considered might include the following:

- Have other outcome measures for the goal of achieving fluid balance been met?

- Does the client understand and comply with planned fluid intake?
- Is all urinary output being measured?
- Are unusual or excessive amounts of fluid being lost by another route (e.g., gastric suction, excessive perspiration, fever, rapid respiratory rate, wound drainage)?
- Are prescribed medications being taken or administered as ordered?

NURSING CARE PLAN Decreased Fluid Volume

ASSESSMENT DATA	NURSING DIAGNOSIS	DESIRED OUTCOMES*
NURSING ASSESSMENT Merlyn Chapman, a 27-year-old sales clerk, reports weakness, malaise, and flu-like symptoms for 3–4 days. Although thirsty, she is unable to tolerate fluids because of nausea and vomiting, and she has liquid stools 2–4 times per day.	Decreased fluid volume related to nausea, vomiting, and diarrhea as evidenced by decreased urine output, increased urine concentration, weakness, fever, decreased skin or tongue turgor, dry mucous membranes, increased pulse rate, and decreased blood pressure	**Fluid Balance [0601]** as evidenced by not compromised: • 24-hour intake and output balance • Urine specific gravity • Blood pressure • Pulse rate • Temperature • Skin turgor • Moist mucous membranes

Physical Examination	Diagnostic Data
Height: 160 cm (5′3′′)	Urine specific gravity: 1.035
Weight: 66.2 kg (146 lb)	Serum sodium 145 mEq/L
Mild fever: 38.6°C (101.5°F)	Serum potassium 3.2 mEq/L
Pulse: 96 beats/min	Chest x-ray negative
Respirations: 24/min	
Scant urine output	
BP: 102/84 mmHg	
Dry oral mucosa, furrowed tongue, cracked lips	

NURSING INTERVENTIONS*/SELECTED ACTIVITIES	RATIONALE
Fluid Management [4120]	
Weigh daily and monitor trends.	*Weight helps to assess fluid balance.*
Maintain accurate I&O record.	*Accurate records are critical in assessing the client's fluid balance.*
Monitor vital signs as appropriate.	*Vital sign changes such as increased heart rate, decreased blood pressure, and increased temperature indicate hypovolemia.*
Give fluids as appropriate.	*As her nausea decreases encourage oral intake of fluids as tolerated, again to replace lost volume.*
Administer IV therapy as prescribed.	*Mrs. Chapman will probably require IV replacement of fluid. This is especially true because her oral intake is limited because of nausea and vomiting.*

Evaluation

Outcomes met. Ms. Chapman required fluid replacement of a total of 5 liters. Her blood pressure increased to 122/74 mmHg, pulse rate decreased to a resting level of 74 beats/min, and respirations decreased to 12/min. Her urine output increased as the fluid was replaced and was adequate at $>$ 0.5 mL/kg per hour by the time of discharge. The urine specific gravity was 1.015. Lab work on the day of discharge was K^+: 3.8 and Na^+: 140. She had elastic skin turgor and moist mucous membranes. She was taking oral fluids and was able to discuss symptoms of decreased fluid volume that would necessitate her calling her healthcare provider.

*The NOC # for desired outcomes and the NIC # for nursing interventions and selected activities are listed in brackets following the appropriate outcome or intervention. Outcomes, interventions, and activities selected are only a sample of those suggested by NOC and NIC and should be further individualized for each client.

APPLYING CRITICAL THINKING

1. Offer suggestions for ways to help Mrs. Chapman increase her oral intake.

2. Mrs. Chapman asks why you weigh her every morning. How do you respond?

Answers to Applying Critical Thinking questions are available on the faculty resources website. Please consult with your instructor.

CONCEPT MAP

Decreased Fluid Volume

Chapter 51 Review

CHAPTER HIGHLIGHTS

- A balance of fluids, electrolytes, acids, and bases in the body is necessary for good health.
- Body fluid is divided into two major compartments: intracellular fluid (ICF) inside the cells and extracellular fluid (ECF) outside the cells.
- ECF is subdivided into two compartments: intravascular (plasma) and interstitial. It constitutes about one-third of total body fluid.
- ECF is in constant motion throughout the body. It is the transport system that carries nutrients to and waste products from the cells.
- The percentage of total body fluid varies according to an individual's age, body fat, and gender. The younger an individual is, and the less body fat present, the greater the proportion of body fluid; post-adolescent females have a smaller percentage of fluid in relation to total body weight than men.
- There are two types of body electrolytes (ions): positively charged ions (cations) and negatively charged ions (anions).
- The principal ions of ECF are sodium (cation), chloride (anion), and bicarbonate (anion); the principal ions of ICF are potassium and magnesium (cations), and phosphate and sulfate (anions).
- Fluids and electrolytes move among the body compartments by osmosis, diffusion, filtration, and active transport.
- The major fluid pressures exerted as part of the movement of fluid and electrolytes from one compartment to another are osmotic pressure and hydrostatic pressure.
- The three sources of body fluid are liquids and food, which are ingested, and the oxidation of food. Fluid intake is regulated by the thirst mechanism.
- Fluid output occurs chiefly through excretion of urine, although body fluid is also lost through sweat, feces, and respiration.
- In healthy adults, measurable fluid intake and output should balance (about 1500 mL per day). The output of urine normally approximates the oral intake of fluids. Water from food and oxidation is balanced by fluid loss through urine, feces, and insensible losses, such as losses through the skin as perspiration.
- A number of body systems and organs are involved in regulating the volume and composition of body fluids: the kidneys, lungs, the cardiovascular and gastrointestinal systems, and the endocrine system. The kidneys are the primary regulator of fluid and electrolyte balance.
- Substances such as antidiuretic hormone, the renin-angiotensin-aldosterone system, and atrial natriuretic factor are also involved in maintaining fluid balance.
- The acid–base balance (pH range) of body fluids is maintained within a precise range of 7.35 to 7.45.
- Acid–base balance is regulated by buffers, which neutralize excess acids or bases; the lungs, which eliminate or retain carbon dioxide, a potential acid; and the kidneys, which excrete or conserve bicarbonate and hydrogen ions.
- Factors that influence an individual's fluid, electrolyte, and acid–base balance include age, sex, body size, environmental temperature, and lifestyle. Illness, trauma, surgery, and certain medications can place individuals at risk for fluid, electrolyte, and acid–base imbalances.
- Fluid imbalances include fluid volume deficit (FVD), also referred to as hypovolemia; fluid volume excess (FVE), also referred to as hypervolemia; dehydration, a deficit in water and an increase in serum sodium level; and overhydration, an excess of water and decrease in serum sodium level.
- Acid–base imbalance occurs when the normal 20-to-1 ratio of bicarbonate to carbonic acid is upset. Imbalances may be either respiratory or metabolic in origin; either can result in acidosis or alkalosis.
- Fluid, electrolyte, and acid–base imbalances are most accurately determined through laboratory examination of blood plasma.
- Assessment relative to fluid, electrolyte, and acid–base balances includes (a) a nursing history; (b) physical examination of the skin, oral cavity, eyes, jugular vein, veins of the hand, and the neurologic system; (c) measurement of body weight, vital signs, and fluid intake and output; and (d) diagnostic studies of blood and urine.
- A nursing history includes data about the client's fluid and food intake; fluid output; signs of fluid, electrolyte, and acid–base imbalances; and medications, therapies, or disease processes that may disrupt these balances.
- Nursing diagnoses that relate specifically to fluid, electrolyte, and acid–base imbalances include decreased fluid volume, increased fluid volume, potential for fluid volume imbalance, and altered gas exchange. Other diagnoses that may be relevant are altered skin integrity, inadequate cardiac output, impaired tissue perfusion, and inadequate physical energy.
- In many instances, fluids and electrolytes can be provided orally to clients who are experiencing or at risk of developing decreased fluid volume. The nurse needs to establish with the client a 24-hour plan for ingesting the necessary fluids and to respect the client's fluid preferences.
- For clients with fluid retention, fluids may need to be restricted; a schedule and short-term goals that make the fluid restriction more tolerable need to be developed.
- For clients experiencing excessive fluid losses, the administration of fluids and electrolytes intravenously is necessary. Meticulous aseptic technique is required when caring for clients with IV infusions.
- Preventing complications such as infiltration, extravasation, and phlebitis is an important aspect of IV therapy.
- The administration of blood transfusions involves accurately matching and identifying the blood for the individual, correctly identifying the recipient, and monitoring the client throughout the procedure for transfusion reactions.

TEST YOUR KNOWLEDGE

1. An older nursing home resident has refused to eat or drink for several days and is admitted to the hospital. The nurse should expect which assessment finding?
   1. Elevated blood pressure
   2. Weak, rapid pulse
   3. Moist mucous membranes
   4. Jugular vein distention
2. A man brings his elderly wife to the emergency department. He states that she has been vomiting and has had diarrhea for the past 2 days. She appears lethargic and is complaining of leg cramps. What should the nurse do first?
   1. Start an IV.
   2. Review the results of serum electrolytes.
   3. Offer the woman foods that are high in sodium and potassium content.
   4. Administer an antiemetic.
3. The nurse administers an IV solution of D_5 1/2NS to a postoperative client. This is classified as what type of intravenous solution?
4. An older client comes to the emergency department experiencing chest pain and shortness of breath. An arterial blood gas is ordered. Which ABG results indicate respiratory acidosis?
   1. pH 7.54; $PaCO_2$ 28 mmHg; HCO_3 22 mEq/L
   2. pH 7.32; $PaCO_2$ 46 mmHg; HCO_3 24 mEq/L
   3. pH 7.31; $PaCO_2$ 35 mmHg; HCO_3 20 mEq/L
   4. pH 7.50; $PaCO_2$ 37 mmHg; HCO_3 28 mEq/L
5. The intake and output (I&O) record of a client with a nasogastric tube who has been attached to suction for 2 days shows greater output than input. Which nursing diagnoses are most applicable? Select all that apply.
   1. Decreased fluid volume
   2. Potential for decreased fluid volume
   3. Dry oral mucous membranes
   4. Altered gas exchange
   5. Inadequate cardiac output
6. Which client statement indicates a need for further teaching regarding treatment for hypokalemia?
   1. "I will use avocado in my salads."
   2. "I will be sure to check my heart rate before I take my digoxin."
   3. "I will take my potassium in the morning after eating breakfast."
   4. "I will stop using my salt substitute."
7. An older man is admitted to the medical unit with a diagnosis of dehydration. Which sign or symptom is most indicative of a sodium imbalance?
   1. Hyperreflexia
   2. Mental confusion
   3. Irregular pulse
   4. Muscle weakness
8. The client's arterial blood gas results are pH 7.32; $PaCO_2$ 58; HCO_3 32. The nurse knows that the client is experiencing which acid–base imbalance?
   1. Metabolic acidosis
   2. Respiratory acidosis
   3. Metabolic alkalosis
   4. Respiratory alkalosis
9. A client is admitted to the hospital for hypocalcemia. Nursing interventions relating to which system would have the highest priority?
   1. Renal
   2. Cardiac
   3. Gastrointestinal
   4. Neuromuscular
10. The nurse would assess for signs of hypomagnesemia in which of the following clients? Select all that apply.
    1. A client with renal failure
    2. A client with pancreatitis
    3. A client taking magnesium-containing antacids
    4. A client with excessive nasogastric drainage
    5. A client with chronic alcoholism

UNIT 10

Meeting the Standards

This unit discusses the fundamentals of physiologic health including activity and exercise, sleep, pain management, nutrition, urinary and fecal elimination, oxygenation, circulation, fluid and electrolyte balance, and acid–base balance. Most clients in the acute care setting will have one or more issues related to these physiologic requirements and the nurse must be alert to the client's needs to prevent complications from developing.

CLIENT: Agnes AGE: 71
CURRENT MEDICAL DIAGNOSES: Fractured left hip

Medical History: Agnes is a healthy and active woman who lives alone. Agnes and her sisters decided it would be fun to go roller skating, and she fell and fractured her left hip. The fracture was diagnosed by x-ray in the emergency department. She underwent open reduction of the fracture and was admitted to the orthopedic unit of the hospital. She will be transferred to a rehabilitation facility once her condition has stabilized. Agnes has a 30-year history of hypertension that she controls with diet and atenolol 50 mg once daily and hydrochlorothiazide 25 mg once per day.

Personal and Social History: Agnes is single and has no children, but she has many friends as well as two sisters and a brother who live nearby. Even in the emergency department after hearing the diagnosis, she and her sisters have been laughing about what fun it will be telling people she broke her hip roller skating. She has a wonderful sense of humor and is often heard laughing. She retired 6 years ago after having worked for 45 years as a pediatric nurse.

Questions

American Nurses Association Standard of Practice #3 is Outcomes Identification: *The registered nurse identifies expected outcomes for a plan individualized to the healthcare consumer or the situation.*

1. Develop an expected outcome for this client related to chapters in this unit including activity and exercise, pain management, fecal elimination, and circulation.
2. What risks can you identify for this client related to activity and exercise, sleep, nutrition, and oxygenation?

American Nurses Association Standard of Practice #4 is Planning: *The registered nurse develops a plan that prescribes strategies to attain expected, measurable outcomes for consumer, family, and others as appropriate.*

3. When planning care with Agnes related to activity and exercise, pain management, nutrition, fecal elimination, oxygenation, and circulation, establish the priorities of care.

American Nurses Association Standard of Practice #5A is Coordination of Care: *The registered nurse coordinates care delivery.*

4. Of activity and exercise, sleep, pain management, nutrition, urinary elimination, fecal elimination, oxygenation, circulation, and fluid, electrolyte, and acid–base balance, which one carries the greatest risk to Agnes's independence and quality of life?
5. What actions can the nurse take to promote and maximize Agnes's independence?

American Nurses Association. (2015). *Nursing: Scope and standards of practice* (3rd ed.). Silver Spring, MD: Author.

Answers to Meeting the Standards Questions are available on the faculty resources site. Please consult with your instructor.

APPENDIX A

Answers to Test Your Knowledge

CHAPTER 1 Historical and Contemporary Nursing Practice

1. **Answer:** 1, 4, and 5. **Rationale:** Option 2, Florence Nightingale, contributed to the nursing care of soldiers in the Crimean War. Option 3, Fabiola, used her wealth to provide houses of caring and healing during the Roman Empire. **Cognitive Level:** Knowledge. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-1.
2. **Answer:** 2, 3, and 5. **Rationale:** State boards of nursing set minimum educational requirements for licensure. Professional organizations establish educational criteria for program accreditation. The National Council of State Boards of Nursing conducts practice studies and creates the NCLEX-RN®. Neither physicians (option 1) nor hospital administrators (option 4) are involved in setting nursing curricula. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-3.
3. **Answer:** 2. **Rationale:** Person (individual or client), environment, health, and nursing are relevant when providing care for any client whether in the hospital, at home, in the community, or in elementary school systems. These elements can be used to understand diseases, conduct and apply research, and develop nursing theories, as well as implement the nursing process. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-5.
4. **Answer:** 2. **Rationale:** Continuing education refers to formalized experiences designed to enhance the knowledge or skill of practitioners. The other answers are examples of in-service education, which is designed to upgrade the knowledge or skills of current employees with regard to the specific setting, and is usually less formal in presentation. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 1-7.
5. **Answer:** 3. **Rationale:** Health promotion focuses on maintaining normal status without consideration of diseases. Option 1 is an example of illness prevention. Option 2 is aesthetic (i.e., not needed for health promotion or disease prevention). Option 4 focuses on disease detection. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-9.
6. **Answer:** 3. **Rationale:** All are noted nurses. Linda Richards was America's first trained nurse, and Mary Mahoney was America's first African American trained nurse. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-1.
7. **Answer:** 2. **Rationale:** Option 1, the advanced beginner, demonstrates marginally acceptable performance. Option 3, the proficient practitioner, has 3 to 5 years of experience and has developed a holistic understanding of the client. Option 4, the expert practitioner, demonstrates highly skilled intuitive and analytic ability in new situations. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-14.
8. **Answer:** 4. **Rationale:** The National Student Nurses' Association developed the *Code of Academic and Clinical Conduct* for nursing students in 2001. Option 1, ANA, developed *Standards of Nursing Practices*. Option 2, NLN, focuses on nursing education. Option 3, the American Association of Colleges of Nursing (AACN), is the national organization that focuses on the advancement and maintenance of America's baccalaureate and higher degree nursing education programs. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-16.
9. **Answer:** 1. **Rationale:** All will impact nursing but not necessarily the supply and demand issue. The aging population contributes to more older adults needing specialized care because of chronic illnesses (increasing the demand). Fewer nursing faculty to educate students and fewer nurses practicing because of retirement contribute to the decreasing supply. **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-15.
10. **Answer:** 2. **Rationale:** All of the expanded roles function as healthcare advocates and all could work with individuals affected by violence. However, the forensic nurse specifically integrates forensic skills into nursing practice. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-12.

CHAPTER 2 Evidence-Based Practice and Research in Nursing

1. **Answer:** 4. **Rationale:** Trial and error is not considered valid evidence, and may even be harmful to clients. Clinical experience (option 1), the opinions of experts (option 2), and client values and preferences (option 3) are all considered valid evidence in EBP. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-3.
2. **Answer:** 1. **Rationale:** Quantitative research collects numerical data. Sleep deprivation can be defined by numbers of hours without sleep and wound healing can be measured by the size of the wound in relation to a period of time. While some of the other options may be calculated using sophisticated numerical processes, they are not as easily measured and may be more appropriate for qualitative research methods. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-4.
3. **Answer:** 3. **Rationale:** This study investigates the subjective experience of stress, through the collection of narrative data. Options 1, 2, and 4 are examples of quantitative research using numbers and values. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-4.
4. **Answer:** 2. **Rationale:** The key purpose of a study's methodology is to generate data that are reliable and valid; thus controlling extraneous variables is a major function. The hypotheses that are tested are formed during the problem identification phase of a study (option 1). Grants and funding sources are not related to methodology (option 3). Protecting participants' rights

(option 4) is an important consideration, but not the key purpose of a methodology. **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-5.

5. **Answer:** 2. **Rationale:** PICO stands for patient or client, population, or problem; intervention; comparison; and outcome. These are helpful components of a research question and help to identify key terms for a literature search. Options 1, 3, and 4 are incorrect. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-5.
6. **Answer:** 2. **Rationale:** Since the primary purpose of research is to improve the quality of client care, the nurse should determine if published research results are applicable to the specific client population. Published studies may have flawed designs, data collection, or analysis (option 1). Although more than one well-conducted study with similar findings supports usefulness of the results, applicability must still be determined for the specific client population (option 3). It is not realistic for the nurse to rerun the raw data to check the results of the study (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-6.
7. **Answer:** 1. **Rationale:** A research critique is the thoughtful consideration of a study's strengths and weaknesses, and how these affect the quality and usefulness of study results. Options 2 and 3 describe elements of a research critique. The summary of a study and its key findings (option 4) is an abstract. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-5.
8. **Answer:** 4. **Rationale:** The right to self-determination means that participants feel free of constraints, coercion, or any undue influence to participate in a study. There is not enough information given to indicate if any of the other rights in options 1, 2, and 3 have been violated. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-7.
9. **Answer:** 3, 2, 1, 5, 4, 6. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-2.
10. **Answer:** 3. **Rationale:** There may have been unique aspects to this research that would not be applicable in a different setting or with different clients. Not all research is flawed (option 1) and it may or may not have taken cost into consideration (option 2). Research is not limited to the study of physiologic problems (option 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-1.

CHAPTER 3 Legal Aspects of Nursing

1. **Answer:** 3. **Rationale:** This is the best answer because the nurse is assessing the client's level of knowledge as a result of the discussion with the primary care provider. Based on this assessment, the nurse may initiate other actions (e.g., call the primary care provider if the client has many questions). In option 1, the nurse is not assessing if the client received enough information to give consent. Option 2 is one way to assess the client's level of knowledge regarding the procedure. However, it is not the best approach because it is a closed-ended question, asking for only a "yes" or "no" response. Option 3 provides more information from the client in his or her own words. The statement in option 4 is true; however, the nurse should first verify if the client received enough information to give consent. After the assessment, this statement may be appropriate but the assessment needs to be done first. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 3-4.
2. **Answer:** 4. **Rationale:** Battery is the willful touching of an individual without permission. Another name for an unintentional tort is malpractice or professional negligence. This situation is an *intentional* tort because the nurse executed the act on purpose. Assault is the attempt or threat to touch another individual unjustifiably or without permission. Invasion of privacy injures the feelings of the individual and does not take into consideration how revealing information or exposing the client will affect the client's feelings. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 3-10.
3. **Answer:** 2. **Rationale:** The nurse should call the individual who wrote the order for clarification. Administering the medication is incorrect because knowing the dose is outside the normal range and not questioning the order could lead to client harm and liability for the nurse. Calling the pharmacist is not the best answer because it will not solve the problem, and the nurse needs to seek clarification from the individual who wrote the order. The nurse should suspend administration but not refuse to administer the medication until the issue is resolved. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 3-7.
4. **Answer:** 1. **Rationale:** All elements such as duty, foreseeability, causation, harm, injury, and damages must be present for professional negligence to be proven. The nurse is a licensed professional responsible for individual actions. Notifying the primary care provider does not exempt the nurse from liability. Because it is apparent the standard of practice was not performed, a breach of duty does exist. Violation or omission of the standard of practice resulted in an excessive dosage. Therefore, foreseeability is present; however, no harm occurred to the client. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 3-9.
5. **Answer:** 4. **Rationale:** A sterile, invasive procedure that places the client at significant risk for infection is generally outside the scope of practice of a AP. Even though the AP is a nursing student, the agency job description should be followed. The job description is the standard of care in this situation. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 3-14.
6. **Answer:** 3. **Rationale:** A DNR order only controls CPR and similar lifesaving treatments. All other care continues as previously ordered. Competent clients can still decide about their own care (including the DNR order). Nothing about the DNR order is related to when the client may die. Because clients' medical conditions and their views of their lives can change, a new DNR order is required for each admission to a healthcare agency. Once admitted, that order stands until changed or until it expires according to agency policy. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 3-7.
7. **Answer:** 3. **Rationale:** The only individual entitled to information without written consent is the client and those providing direct care. The nurse has open access to information regarding assigned clients only. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 3-11.
8. **Answer:** 1, 2, and 5. **Rationale:** The nurse is subject to the limitation of the state law and should be familiar with the Good Samaritan laws in the specific state. Gross negligence would be described by the individual state law. Unless there is another equally or more qualified individual present, the nurse needs to stay until the injured individual leaves. The nurse should ask someone else to call or go for additional help. Since there was no prior agreement, the nurse cannot accept compensation. Also, the nurse is not employed by the accident victim. The same client rights apply at the scene of an accident as those in the workplace. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 3-13.

9. **Answer:** 1, 3, and 4. **Rationale:** Interacting with others (versus isolating self from others) and setting limits on the number of hours working are positive behaviors and not indicative of possible impairment. The other options are warning signs for impairment. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 3-6.
10. **Answer:** 2 and 3. **Rationale:** Standards of practice require a complete assessment. A nurse needs to be sure the client's needs have been met. They both can impact client safety and do not follow standards of care. The other options meet the standards of practice. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 3-7.

CHAPTER 4 Values, Ethics and Advocacy

1. **Answer:** 1. **Rationale:** A nurse's actions in an ethical dilemma must be defensible according to moral and ethical standards. The nurse may have strong personal beliefs but distancing oneself from the situation does not serve the client (option 2). A team is not always required to reach decisions (option 3), and the nurse is not obligated to follow the client's wishes automatically when they may have negative consequences for self or others (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 4-2.
2. **Answer:** 2. **Rationale:** The nurse has an ethical responsibility to act only when actions are safe or risks minimized. This nurse is putting the client at unnecessary risk for a medication error. Many medical practices are controversial but not necessarily unethical (option 1). The nurse should follow agency policy. Although some may view nurses' strikes as unethical, supporting others who are striking is a personal decision (option 3). Although a client statement in confidence to a nurse may have ethical overtones, it does not automatically constitute an ethical dilemma. Since the assigned healthcare provider is a member of the team, principles of confidentiality do not include him or her (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 4-4.
3. **Answer:** 1. **Rationale:** Autonomy is the client's (or surrogate's) right to make his or her own decision. The nurse is obliged to respect a client's or significant other's informed decision. These parents may modify their decision as time goes on and the child's condition, or their feelings, change. This situation is not clearly one of nonmaleficence (do no harm) in option 2 or beneficence (do good) in option 3 since there are many aspects of both. If the child appeared to be suffering or an effective treatment was being denied, these principles might apply. Justice (fairness) generally applies when the rights of one client are being balanced against those of another client (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 4-3.
4. **Answer:** 3. **Rationale:** In values clarification, clients are assisted to think about the factors that influence their beliefs and decisions. Any judgmental statement that reflects the rightness or wrongness of the client's thoughts or actions will impede this process (options 1, 2, and 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 4-2.
5. **Answer:** 4. **Rationale:** A major role of the client advocate is to mediate between conflicting parties. The nurse needs to assess the situation before offering an intervention. Informing the family is an intervention without assessment (option 1). If the primary care provider sends the client home, the nurse has not acted to assist in resolving or reducing the conflict (option 2). If the nurse assists in resolving or reducing the conflict, the added expense of an attorney may not be needed. However, legal action should be a last resort (option 3). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 4-5.
6. **Answer:** 4. **Rationale:** The nurse is obliged to design care and to act according to the professional code of ethics even if the nurse holds different values. The client's need for value-based care takes precedence over the nurse's values; however, nurses can choose not to participate in care with which they have conflicting values (options 1 and 2). The client outcome can be the same even when different moral frameworks are used (option 3). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 4-1.

CHAPTER 5 Healthcare Delivery Systems

1. **Answer:** 3. **Rationale:** Actions such as diet modification that help to prevent an illness or detect it in its early stages are primary preventions. Treatment of a disease such as with antibiotic therapy (option 1) or surgery (option 4) is secondary prevention, while rehabilitation efforts following an illness (option 2) are considered tertiary prevention. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** N/A. **Learning Outcome:** 5-1.
2. **Answer:** 2. **Rationale:** City, county, state, or federal government funds pay for health department and agency activities aimed at the global health of the community. Hospitals may provide a variety of wellness and clinic programs in addition to inpatient services (option 1). Surgery may be performed in outpatient surgery centers and physicians' offices in addition to within hospitals (option 3). Skilled nursing, extended care, and long-term care facilities provide care to clients of all ages who require rehabilitation or subacute care. This is not necessarily related to insurance coverage for hospital stays (option 4). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 5-2.
3. **Answer:** 1. **Rationale:** Primary care providers are limited to generalist physicians and advanced practice nurses. In some cases a gynecologist may qualify as a primary care provider and in other cases not. Physical therapists (option 2) do not have a scope of practice broad enough to serve as primary care providers. Case managers or discharge planners (option 3) and pharmacists (option 4) are not responsible for providing direct client care. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 5-3.
4. **Answer:** 2. **Rationale:** When people have inadequate insurance for health costs, they tend to avoid early and preventive care. This results in eventual use of much more costly resources such as emergency rooms. Methods to provide minimum levels of insurance coverage have been successful in other countries. The number of children is increasing, but in the United States and Canada, this is a nonmodifiable factor (option 1). Also, the majority of healthcare costs are incurred by adults and older adults who tend to have multiple and chronic health conditions. There is currently a significant shortage of nurses and maldistribution of physicians so reducing their numbers would only worsen the problem (option 3). Competition among manufacturers is more likely to cause costs to fall than to rise (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 5-4.
5. **Answer:** 4. **Rationale:** A health maintenance organization involves a set monthly membership fee and predictable visit or deductible costs. Medicare covers a minimal number of preventive and outpatient services so the cost cannot be anticipated (option 1). Individual fee-for-service insurance is perhaps the most costly to the client, with potentially large differences between the amount of coverage the insurance company pays

and the provider's charges (option 2). PPOs are less costly than fee-for-service entities, but more expensive than HMOs (option 3). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Management. **Nursing Process:** Planning. **Learning Outcome:** 5-6.

CHAPTER 6 Community Nursing and Care Continuity

1. **Answer:** 1. **Rationale:** The Pew Commission identified the need for modern healthcare providers to be proficient in the use of technology. Care should be emphasized in primary, rather than tertiary, settings (option 2). The commission also identified the need for contemporary (not traditional) clinical strategies (option 3) and for collaborative decision-making with clients (option 4). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 6-5.
2. **Answer:** 2. **Rationale**: In community-based healthcare, clients are cared for according to their geographic locations such as where they live or work, rather than at a major medical center or similar provider setting, which facilitates access. The other options are incorrect because emphasis is more on client wellness and prevention than on illness and may be paid for through any of the usual forms of insurance or payment (including managed care, private pay, or welfare). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 6-4.
3. **Answer:** 2. **Rationale:** In collaboration, each member of the team, including the client, participates in sharing ideas and reaching consensus on the best plan of care. The team is generally led by the healthcare professional most skilled in the client's specific areas of need (option 1). Once the plan is established, it may be implemented by any member of the team or a designate at an appropriate time and place (option 3). It is not necessarily assigned by the nurse (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 6-6.
4. **Answer:** 4. **Rationale:** Effective discharge planning would have included an assessment of home care needs prior to the client leaving the hospital. The kind of care is determined before the client leaves the current setting. That is why it is called discharge "planning." Following a thorough assessment, the client would be taught self-care strategies and a basic plan of care for the coming days (option 3). Obtaining medications and a ride home does not indicate the client possesses the knowledge and skills needed to manage care after discharge (option 2). If the client will need care at home, those referrals would be made by the discharge planner and communicated to the client. Option 4 indicates the client knows and accepts these referrals. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 6-7.
5. **Answer:** 4. **Rationale:** The home health nurse more commonly works with one client or family at one time—addressing their particular needs, which may be similar to or different from those of others. The community health nurse will focus on activities that influence the larger group of individuals affected. These include options 1 and 2—prevention and monitoring of infectious disease plus actions that will promote health for multiple affected individuals (e.g., food, water, and shelter). **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 6-5.

CHAPTER 7 Home Health Nursing Care

1. **Answer:** 3. **Rationale:** Although hospitals have recently become more welcoming to families, a major strength of home care is the involvement and proximity of loved ones. Curative and lifesaving approaches may be used both at home and in the hospital (option 1). An asset of home care nurses is their ability to manage complex symptoms (option 2). This includes expertise in pain management, but the same legal strategies are available in either in-home care or hospitals (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 7-2.
2. **Answer:** 1. **Rationale:** Assuming the client is medically stable, feeding and bathing are tasks within the aide's abilities. Options 2, 3, and 4 are incorrect because teaching the client about or adjusting medications (and oxygen is considered a medication) and performing assessments are duties restricted to the registered nurse. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 7-4.
3. **Answer:** 2. **Rationale:** The nurse needs to encourage the client to express feelings or thoughts that led to the refusal so that misunderstandings can be clarified and other possible solutions explored. The nurse should apply the principle that all behavior has meaning. Otherwise, the nurse is intervening before assessing the situation (option 1). The approach in option 3 did not work the first time. A reason for the refusal needs to be explored. Option 4 is almost a threat and has a paternalistic implication. Clients are entitled to make informed decisions to perform or not perform recommended activities. Notifying the primary care provider is implementing an intervention before the nurse has done an assessment. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 7-5.
4. **Answer:** 1. **Rationale:** If the caregiver's own health is becoming threatened, it may be a sign of overload. It would be appropriate for the caregiver to ask for assistance from others (option 2), or to ask for clarification of ways he or she can assist the client (option 3). Sadness related to a poor prognosis would be a normal and expected response as long as it does not evolve into depression (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 7-7.
5. **Answer:** 4. **Rationale:** A physician's authorization of the plan of care is needed before home healthcare by a nurse can be initiated. Insurance coverage is not required, although the agency may need proof of the client's ability to pay if insurance is not available or adequate (option 1). Many clients benefit from home healthcare even if there is no in-home caregiver present or needed (option 2). The health problem for which home care is needed may be chronic or acute and may necessitate preventive, curative, or palliative therapy (option 3). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 7-3.
6. **Answer:** 1, 3, and 6. **Rationale:** Nurses may work with hospice clients as a subset of home health. In home healthcare, nurses care for both client and family and perform physical, psychosocial, and emotional interventions. Skilled nursing facilities are not considered locations for home health nursing care (option 2). Home healthcare can include high-tech equipment and procedures (option 4). Clients may have home care whether or not they can afford other healthcare (option 5). **Cognitive Level:** Remembering. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 7-4.
7. **Answer:** 4. **Rationale:** The emergency response necklace only works within the client's home in proximity to the base station. It will not activate away from home. The client needs to wear it at all times when home. It can be worn when away from home but the client must understand that activating it when away will not summon assistance. It is appropriate for the client to wear a medical alert bracelet at all times (option 1) and have a list of medications posted on the refrigerator (option 2). Area rugs should be removed if clients could trip

on them (option 3). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 7-6.

CHAPTER 8 Electronic Health Records and Information Technology

1. **Answer:** 1, 2, 4, and 5. **Rationale:** Technology can facilitate almost every aspect of nursing administration. Both individual employee and overall institutional compliance with accreditation standards and criteria are tracked (option 1). Most common medical diagnoses and costs of all care can be retrieved from the electronic databases (option 2). Financial performance, as well as the results of client satisfaction surveys, are common computer applications (options 4 and 5). Option 3 is incorrect because, although the results of performance appraisals may be entered into a computer program for tracking purposes, it would be an overstatement to say that this indicates which employees are doing the best job since that is a very subjective determination. Computers do a better job in providing concrete, quantitative data. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 8-4.
2. **Answer:** 3. **Rationale:** Control over who has access to confidential computerized data is the greatest concern. Computer hackers can bypass codes and gain access to personal information, which could result in identity theft. The benefits often outweigh the cost (option 1). Computerized data can be much more accurate than paper-and-pencil data (option 2). Due to ease of making copies and backups, electronic data can last forever (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 8-2.
3. **Answer:** 4. **Rationale:** Since learners may do their online work at different times and do much of their work offline, it may be harder for them to feel and act like a class group. The courses are often self-paced and, thus, may take a longer or shorter time to complete than on-campus courses (option 1). Interpersonal communication is possible through email and chat, plus audio and video file sharing allow learners to see and hear the faculty as well as one another (option 2). For most web-based courses, learners may log on at their convenience (option 3). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 8-1.
4. **Answer:** 3. **Rationale:** Although all steps of the research process can be accomplished with and without computers, electronic analysis of data helps ensure accuracy and speeds the process immensely. **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 8-5.
5. **Answer:** 1. **Rationale:** Each website is different and the practitioner is compelled to evaluate the site and the treatment to determine if it is evidence based, safe, and appropriate for the client. Website-described treatments often report results of extensive research (option 2). One of the most important advantages of posting treatment information and results on the internet is that many different individuals can determine if the treatment is useful for their clients (option 3). Some websites are actually advertising, but many are sponsored by legitimate organizations such as the National Cancer Institute (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 8-3.

CHAPTER 9 Critical Thinking and Clinical Reasoning

1. **Answer:** 2. **Rationale:** The nurse has inferred and concluded something that is beyond the available information (and in this case may not be accurate). The prescription and the diarrhea are facts (option 1). It would be judgment and opinion if the nurse stated that the laxative would make the diarrhea worse and should not be given (options 3 and 4). (*Note:* Critical thinking will cause this nurse to examine the assumptions made and gather more data before acting.) **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 9-1.
2. **Answer:** 1. **Rationale:** The nurse recognizes that many assumptions (beliefs) could interfere with the client eating—such as that the food presented is not culturally appropriate. These assumptions must be clarified with the process of clinical reasoning. Options 2 and 3 reach conclusions not supported by the facts. In option 4, the nurse has made a judgment or has an opinion that may not be accurate. Also, the nurse is acting without assessment. Implementation should be preceded by assessment. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 9-2.
3. **Answer:** 2. **Rationale:** Reviewing evidence-based literature and identifying similarities in the clinical manifestations of symptoms is an act of clinical reasoning. Past experiences in care enhance the nurse's ability to recognize and respond in the delivery of client-centered care. Clinical judgment in nursing is a decision-making process to ascertain the right action to implement at the appropriate time during client care (option 1). Reflection is the nurse's review of the care provided to determine strategies to improve future care (option 3). Intuition is a problem-solving approach that relies on a nurse's inner sense (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** N/A. **Learning Outcome:** 9-2.
4. **Answer:** 1. **Rationale:** The research method uses a research study-based approach to problem-solving. Trial and error (option 2) and intuition (option 3) would involve unstructured approaches resulting in less predictable results. The nursing process generally uses application of known interventions, previously determined by the scientific (research) process (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 9-5.
5. **Answer:** 4. **Rationale:** It is important to project what problems might interfere with the plan and have appropriate responses prepared to prevent the interferences. The purpose for the decision should have been clear enough at the outset as to not require reexamination at this point (option 1). Clients and families should be consulted early—in the purpose-setting and criteria-setting steps. Criteria should not be set until all significant participants have an opportunity to present their point of view (option 2). Considering various means for reaching the outcomes is the same as examining alternatives (option 3). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 9-4.
6. **Answer:** 2. **Rationale:** The nurse's intuition is like a sixth sense that allows the nurse to recognize cues and patterns to reach correct conclusions. The nurse appropriately obtains vital signs and an oxygen saturation to assess the client's clinical picture more fully. Option 1 supports appropriate nursing actions, but the client's respiratory status should be assessed first. Usually, a physician must order a chest x-ray (option 3). The rapid response team (option 4) may be needed if the client's condition becomes more critical. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementing. **Learning Outcome:** 9-2.
7. **Answer:** 1. **Rationale:** By reconsidering the type of dressing used based on research, the nurse is using integrity. Options 2 and 3 are critical thinking attitudes characterized by an awareness of the limits of one's own knowledge, and being trustworthy. Option 4 indicates an attitude of not being easily swayed by the opinions of others. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 9-4.

8. **Answer:** 1. **Rationale:** Nurses must embrace exploration of the perspectives of individuals from different ages, cultures, religions, socioeconomic levels, and family structures to create environments that support critical thinking. Option 2 relates to nurses who should increase their tolerance for ideas that contradict previously held beliefs. Option 3 is conducted when a nurse benefits from a rigorous personal assessment to determine which attitudes he or she already possesses and which need to be cultivated. Option 4 occurs when nurses find it valuable to attend conferences in clinical or educational settings that support open examination of all sides of issues and respect for opposing viewpoints. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 9-1.
9. **Answer:** 2. **Rationale:** The nurse recognizes the need to obtain further information from the client in order to respond directly to the client's statement. Option 1 passes off the client's educational needs to another practitioner. Options 3 and 4 are nontherapeutic. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 9-5.
10. **Answer:** 4. **Rationale:** A nurse thinks critically, evaluates possible solutions, and uses problem-solving. Intuition (option 1) is not a sufficient basis for implementing wound care when significant data on alternative care strategies are available. Research (option 2) is a more comprehensive rigorous process and not typically implemented while caring for an infected wound. Trial and error (option 3) is unsafe and inappropriate for care of an infected wound. **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 9-5.

CHAPTER 10 Assessing

1. **Answer:** 1. **Rationale:** Identifying problems and needs is part of a nursing diagnosis. For example, a client with difficulty breathing would have constricted airways as manifested by shortness of breath (dyspnea) as a nursing diagnosis. Organizing the family history (option 2) is part of the assessment phase. Establishing goals (option 3) is part of the planning phase. Administering an antibiotic (option 4) is part of the implementation phase. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 10-1.
2. **Answer:** 3. **Rationale:** During assessment, data are collected, organized, validated, and documented. Hypotheses are generated during diagnosing; outcomes are set during planning; and documentation occurs throughout the nursing process. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 10-1.
3. **Answer:** 2. **Rationale:** Primary data come from the client (option 4), whereas secondary data come from any other source (chart, family). Subjective data are covert (reported or an opinion), whereas objective data can be measured or validated (weight—option 1, edema—option 3). If the spouse had stated that the client had eaten only toast and tea, this would be secondary objective (measured) data. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 10-5.
4. **Answer:** 3. **Rationale:** Eliciting feelings requires an open-ended question that does more than seek factual information (option 1) and cannot be answered with a single word (option 2). The family can provide indirect information about the client, but is not most likely to provide the most accurate information (option 4). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 10-8.
5. **Answer:** 4. **Rationale:** Frameworks help the nurse be systematic in data collection. Other members of the healthcare team may use very different conceptual organizing frameworks so data may not correlate (option 1). Cost-effective care (option 2) is more likely to occur with systematic application of the nursing process, but use of a framework for assessment alone may not accomplish this goal. Because the framework is structured and because of the nature of client needs and problems, creativity and intuition in care planning are not assured (option 3). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 10-10.
6. **Answer:** 1. **Rationale:** Assessing provides a database of the client's physiologic and psychosocial responses to his or her health status. Client strengths and problems (option 2) are identified in the diagnosing phase of the nursing process; a care plan is established (option 3) in the planning phase; and care, prevention, and wellness promotion (option 4) are part of the implementing phase. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 10-3.
7. **Answer:** 3. **Rationale:** In validating, the nurse confirms that data are complete and accurate. Subjective data are collected in the collecting activity (option 1), a framework is applied to the data in the organizing activity (option 2), and data are recorded in the documenting activity (option 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 10-4.
8. **Answer:** 1. **Rationale:** The nursing process focuses on client needs. It is dynamic rather than static (option 2), emphasizes client responses rather than physiology and illness (option 3), and is collaborative rather than used exclusively by nurses (option 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 10-4.
9. **Answer:** 4. **Rationale:** Interpreting collected data is necessary to help validate their accuracy. Observing includes the senses of smell, hearing, and touch in addition to vision (option 1). Observing must often be performed simultaneously with other activities (option 2). A systematic approach to observing data helps ensure nothing is missed and the nurse pays attention to the most important data first (option 3). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 10-6.
10. **Answer:** 2, 4, and 5. **Rationale:** The nurse plans the interview so that privacy is observed. A comfortable distance between nurse and client to respect the client's personal space is about 3 feet. Using a standard form will help ensure the nurse doesn't omit gathering any vital information. Lighting should be at a normal level—neither bright nor dim (option 1). The nurse should be at the same height as the client, usually sitting, at approximately a 45° angle facing the client. The nurse standing over the client creates an uncomfortable atmosphere for an interview (option 3). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 10-9.

CHAPTER 11 Diagnosing

1. **Answer:** 2. **Rationale:** In diagnosing, data from assessment (option 1) are analyzed and problems, risks, and strengths are identified before diagnostic statements can be established. Interventions (option 3) are more commonly part of the planning and implementing phases of the nursing process. Cost (option 4) is an important consideration but would be estimated in the planning phase. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 11-4.
2. **Answer:** 2. **Rationale:** Because the venous return is impaired, fluid is static, resulting in swelling. Therefore, decreased venous return is the cause (etiology) of the problem. Increased fluid volume is the nursing diagnosis, and edema of the lower extremity is the sign, symptom, or critical attribute. The cause is known. **Cognitive Level:** Application. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 11-6.

3. **Answer:** 1. **Rationale:** States the relationship between the stem (impairment in caregiver role) and the cause of the problem. Option 2: The diagnostic statement says the same thing as the related factor (falls and collapse). Option 3: It is inappropriate to use medical diagnoses such as stroke within a nursing diagnosis statement. Option 4 is vague. The statement must be specific and guide the plan of care (fatigue may be a result of sleep deprivation and does not direct intervention). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 11-2.
4. **Answer:** 4. **Rationale:** The PES format assists with comprehensive and accurate organization of client data. More efficient planning may or may not reduce healthcare costs. Nursing diagnostic statements should be confirmed with the client but using PES does not ensure this. PES statements can be wellness or illness focused. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 11-5.
5. **Answer:** 1. **Rationale:** A collaborative (multidisciplinary) problem is indicated when both medical and nursing interventions are needed to prevent or treat the problem. If nursing care alone (whether that care involves independent or dependent nursing actions) can treat the problem, a nursing diagnosis is indicated. If medical care alone can treat the problem, a medical diagnosis is indicated. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 11-3.
6. **Answer:** 1. **Rationale:** A risk nursing diagnosis is appropriate when the evidence for the problem indicates that a condition exists that makes the client vulnerable to a problem. A syndrome diagnosis is assigned by a nurse's clinical judgment to describe a cluster of nursing diagnoses that have similar interventions (option 2). Health promotion diagnoses are used when the client seeks to increase well-being but need not currently be well (option 3). An actual diagnosis is used when the client already exhibits the problem (option 4). **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 11-1.
7. **Answer:** 3. **Rationale:** Diagnostic labels are continuously reviewed and revised as indicated by research—much more of which is needed. The original taxonomy has been replaced by Taxonomy II and is no longer based on a nurse theorist (options 1 and 2). New diagnoses are approved by NANDA International's Diagnostic Review Committee, not by a vote of nurses (option 4). **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 11-7.
8. **Answer:** 1, 4, and 5. **Rationale:** A client's movement toward a goal (option 1) or whose behavior is inconsistent with population norms (options 4 and 5) represents a cue that further analysis toward creating a nursing diagnosis is required. Corrected vision (option 2) and bladder and bowel control at age 18 months (option 3) are consistent with population norms. **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 11-4.

CHAPTER 12 Planning

1. **Answer:** 4. **Rationale:** Strategic planning is an ongoing process focused on organizational change rather than individual clients so it is least useful and not relevant in this case. The client requires initial planning because he has just arrived on the orthopedic unit for the first time (option 1). Of the three types of planning that need to be done at this time, initial is the highest priority since he has just had surgery. The client also requires the ongoing type of planning necessary to determine the care appropriate for this shift (option 2). Discharge planning needs to start on admission to ensure adequate client preparation for management of health needs outside the health agency (option 3). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 12-2.
2. **Answer:** 1. **Rationale:** Policy and procedure documents provide data about how certain situations are handled. Standardized care plans (option 2) and standards of care (option 4) are written for groups of clients with similar medical or nursing diagnoses. They generally do not address questions such as hospital routines and nonmedical client needs. *Note:* Even hospital policies are not absolute. Each situation must be analyzed and responded to individually. Orthopedic protocols (option 3) would address elements specifically associated with the surgery, not whether the family slept in the room. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 12-5.
3. **Answer:** 2. **Rationale:** More detailed assessment data and consultation with the client would be needed to absolutely confirm the priority. Postoperative nausea to the level of inhibiting oral intake has the greatest likelihood of leading to complications and requires nursing intervention now. The client's pain level is not extreme considering the recency of the surgery, and pain intervention can be assumed to be effective (option 1). Although the constipation is probably bordering on abnormal, a nursing intervention would most likely begin with oral treatment, which is not possible due to the nausea. More invasive interventions such as an enema or suppository would not be commonly administered the first day postoperative (option 3). Wound infection can occur, but there are no data to indicate that this requires a change in the current plan (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 12-5.
4. **Answer:** 3. **Rationale:** The goal or outcome should state the opposite of the nursing diagnosis stem, and thus healthy intact skin is the reverse condition of altered skin integrity. Turning in bed, applying lotion, and using a special mattress are all interventions that may result in achieving the goal (options 1, 2, and 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 12-8.
5. **Answer:** 3. **Rationale:** Although there may be standard policies or routines for measuring intake and output, the nursing intervention should specify if this is to be done "routinely" or at specific intervals (e.g., q4h). The nurse is also aware, however, that critical thinking indicates that the intake and output should be monitored more frequently than ordered if assessment reveals abnormal findings. **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 12-9.
6. **Answer:** 3, 1, 4, and 2. **Rationale:** In planning, first the nurse sets priorities and then writes goals or outcomes, selects interventions, and then writes the nursing care plan. **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 12-1.
7. **Answer:** 2. **Rationale:** Standardized care plans provide a list of interventions from which the nurse can choose. The plan must still be individualized (option 1). Standardized plans could be longer or shorter than nurse-authored ones (option 3), but have not been approved by any outside accreditor (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 12-3.
8. **Answer:** 1. **Rationale:** Goal statements provide the standard against which outcomes are measured. Nursing diagnoses are prioritized before goals are written (option 2). Both independent and dependent interventions may be appropriate for any goal (option 3). Clarity of the goal does not influence delegation of the intervention (option 4). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 12-6.
9. **Answer:** 4. **Rationale:** NOC outcomes should reflect both the nurse's and the client's values of what is trying to be achieved. The outcomes still must be customized (option 1), but address

only one nursing diagnosis at a time (option 2). Outcomes are narrow or specific end points, not broad (option 3). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 12-7.

10. **Answer:** 1. **Rationale:** Interventions should address the etiology of the nursing diagnosis. Both independent and dependent interventions should be selected if appropriate (option 2) and several interventions may be needed for a single outcome (option 3). Both action and assessment-type interventions can be used (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 12-10.

CHAPTER 13 Implementing and Evaluating

1. **Answer:** 3. **Rationale:** The first step of implementing is reassessing the client to determine that the activity is still indicated and safe. The next action would be to determine if assistance is required (option 2), then implement the intervention (delegating if appropriate) (option 1), and last document the intervention (option 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Implementation. **Learning Outcome:** 13-3.
2. **Answer:** 4. **Rationale:** It is never acceptable practice for the nurse to document a nursing activity before it is carried out. This would be very unsafe because many things can cause an activity to be postponed or canceled and prior charting would be inaccurate, misleading, and potentially dangerous. In a few situations, it may be permissible to chart frequent or routine activities some time following the activities such as at the end of a shift or after a particular interval (e.g., every 4 hours) rather than immediately following the activity. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Implementation. **Learning Outcome:** 13-4.
3. **Answer:** 1. **Rationale:** The desired outcomes and indicator statements reflect the parameters by which success will be measured. The goal can be met even if the nursing activities were not carried out or were ineffective (options 2 and 3). Although the desired outcome, by definition, indicates a change in the client's condition (behavior, knowledge, or attitude), only specific changes (desired outcomes) reflect the success of the care plan (option 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 13-5.
4. **Answer:** 2. **Rationale:** There is no reason to delete (option 1) or modify the nursing diagnosis (option 3) or demote its priority (option 4) because the risk factors that prompted it are still present. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 13-7.
5. **Answer:** 2. **Rationale:** Because this assessment focuses on how care is provided, it is a process evaluation. A structure evaluation (option 1) would focus on the setting (e.g., how well equipment functions), and outcome evaluations (option 3) focus on changes in client status (e.g., whether reported satisfaction levels vary with type of individual who answers the call light). An audit (option 4) would be a chart or document review. **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 13-8.
6. **Answer:** 1. **Rationale:** During implementing, the nurse also assesses and compares with the initial assessment. Evaluating follows implementing (option 2), mobilization of other healthcare teams is a part of implementing (option 3), and evaluating occurs during or immediately after each intervention, not waiting for all interventions to be completed (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 13-1.
7. **Answer:** 3. **Rationale:** This client needs psychosocial support rather than skills related to knowledge (options 1 and 2) or hands-on activity (option 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 13-2.
8. **Answer:** 1, 4, and 5. **Rationale:** Nurses should always have clear rationales for their actions, clients should be given options whenever possible, and client teaching is a constant, integral part of implementing. Primary care provider orders must be critically evaluated and modified to meet individual client needs (option 2). Clients may have nurses provide needed care but should take care of themselves whenever possible since dependency has its own complications (option 3). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 13-4.
9. **Answer:** 2. **Rationale:** Evaluating requires that client behavior be compared to expected outcomes. Goals may be partially met in addition to completely met or unmet (option 1). An outcome may be achieved but not be a direct result of the plan or interventions (option 3). A care plan should be continued, modified, or terminated based on achievement of outcomes (option 4). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 13-6.
10. **Answer:** 4. **Rationale:** Quality improvement (QI) plans corrective actions for problems. QI focuses on process rather than outcomes (option 1) and client care rather than structure (option 2), and aims for improvement rather than confirmation of quality (option 3). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 13-9.

CHAPTER 14 Documenting and Reporting

1. **Answer:** 3. **Rationale:** All of the other answers endanger the client's confidentiality. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 14-1.
2. **Answer:** 1. **Rationale:** Critical pathways work best for clients with one diagnosis. Option 2 is a possibility; however, there may be many individualized needs. Because that information is not available, the best answer is 1. Options 3 and 4 have too many diagnoses to work well with a critical pathway. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 14-3.
3. **Answer:** 2. **Rationale:** It is the most complete answer. It indicates the diagnosis, surgical procedure, condition of the surgical incision, and the pain medication administered along with the time it was administered. Option 1 only indicates the surgical procedure. Option 3 indicates the surgical procedure and the administration of one medication. Option 4 only indicates the client's mental status and breathing on room air. There is no indication of the surgical procedure or diagnosis. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 14-8.
4. **Answer:** 4. **Rationale:** Option 4 is the "best" answer although it could be more complete by adding the response of the primary care provider. Option 1 is too vague because it is not clear if the nurse found the client or was present when the client fell. Also, there is no need to write the word *client* because it is the client's chart. Option 2 is judgmental, revealing a negative attitude toward the client. It would be better to describe specific signs and symptoms such as staggering, slurred speech, and smell of alcohol on breath. Option 3 is too general and can be more specific by charting "2 cm × 3 cm purplish bruise on mid-inner thigh along with color." **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 14-6.
5. **Answer:** 1. Within normal limits; 2. Bathroom privileges; 3. As needed; 4. Diet as tolerated. **Cognitive Level:** Remembering. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 14-6.

6. **Answer:** 2. **Rationale:** The graphic record provides the trend of the vital signs. Option 1, verbal information, is not appropriate for validation assessment that is measurable. This is more appropriate for pain or dizziness. The medication record would not include documentation of blood pressure ranges (option 3). The progress notes (option 4) provide information about how the client is progressing. It may have information about the client's BP if it was a problem. The best answer is option 2. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 14-4.
7. **Answer:** 1, 2, and 4. **Rationale:** Option 3 is incorrect because it could be a HIPAA violation if others hear protected health information. Option 5 is not needed unless it is a concern and it would not be done for every client. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 14-8.
8. **Answer:** 2, 3, and 5. **Rationale:** Option 1: "MS" is on the "Do Not Use" list—the nurse needs to write out morphine sulfate. Option 4 has three errors—should not have a trailing zero after the decimal point; "u" and "SQ" are on the "Do Not Use" list. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 14-7.
9. **Answer:** 1. **Rationale:** Option 1 is the most specific, nonassuming, and nonjudgmental charting. Option 2 could be more specific by describing the lesions and not calling them "burns." Option 3 is making a judgment of elder abuse, and option 4 is also making an assumption that the lesions are from cigarette burns. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 14-6.
10. **Answer:** 1, 2, and 4. **Rationale:** Military time is commonly used; documenting worries or concerns provides clues to other nurses; gossip, unprofessional comments or thoughts, or personnel issues should not be recorded in the client's chart. Option 3 is incorrect because charting should be done as events occur. Waiting until the end of the shift increases the chance of forgetting something. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 14-6.

CHAPTER 15 Caring

1. **Answer:** 2. **Rationale:** This assessment activity gathers more information to help the nurse know the client's usual self-care practices. Option 1 aims to provide comfort. Option 3 is a therapeutic, not an assessment, activity. Option 4 does not meet the aim of knowing the client. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 15-4.
2. **Answer:** 1. **Rationale:** Teaching the client to make self-care decisions at home empowers him to care for his illness. Empowerment is not the primary goal for options 2, 3, and 4. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 15-4.
3. **Answer:** 3. **Rationale:** Roach uses the Six C's of caring in nursing. Swanson's theory includes five caring processes (option 1). Mayeroff was a philosopher who saw caring as "helping the other grow" (option 2). Watson developed the Theory of Human Care, which is the basis for nursing's role in society (option 4). **Cognitive Level:** Remembering. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 15-3.
4. **Answer:** 1. **Rationale:** This situation reflects personal knowing, which is developed through critical reflection on one's own actions and feelings. Aesthetic knowing arises from a deep appreciation of the uniqueness of each individual (option 2). Empirical knowing includes objective observation and scientific theories (option 3). Ethical knowing involves confronting and resolving conflicting values and beliefs (option 4). **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 15-2.
5. **Answer:** 3. **Rationale:** This represents an ethical dilemma. Options 1, 2, and 4 are ways of knowing less clearly related to the situation. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 15-6.
6. **Answer:** 1. **Rationale:** The nurse's presence is most significant in this situation. Assessment (option 2), knowing the client (option 3), and empowering the client (option 4) are not the focus of the nurse's action. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 15-6.
7. **Answer:** 1, 3, and 4. **Rationale:** Options 1, 3, and 4 are healthy options for self-care. Use of alcohol as a way to destress can be unhealthy (option 2). Gossiping is negative energy and should be avoided (option 5). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 15-5.
8. **Answer:** 1. **Rationale:** Empirical knowing is gained from studying scientific models and theories. Aesthetic knowing arises from application in practice (option 2). Personal knowing arises from self-examination (option 3). Ethical knowing arises from confronting conflicting values (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 15-2.
9. **Answer:** 4. **Rationale:** Meditation involves the described behaviors. Storytelling involves communication with others (option 1). Yoga combines various postures with breathing practices (option 2). Music therapy involves listening to music (option 3). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 15-5.
10. **Answer:** 3. **Rationale:** Twenty-five minutes of vigorous activity 3 days a week is the recommendation for a healthy lifestyle. Ten minutes is an insufficient amount of time for moderate exercise (option 1), as is 20 minutes (option 2). Daily vigorous activity for 30 minutes may be too strenuous (option 4), depending on the client's level of conditioning. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 15-6.

CHAPTER 16 Communicating

1. **Answer:** 3. **Rationale:** Nonverbal, gentle touch is an important tool; overstimulation may affect the client in a negative way. Option 1: Written communication requires a higher level of consciousness than verbal. Option 2: The client does not have a hearing problem but lacks the ability to interpret and understand communication. Option 4: Lack of facial expression may increase fear. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 16-7.
2. **Answer:** 3, 1, 2, 4. **Rationale:** During the preinteraction phase (option 3), the nurse gathers information about the client before meeting the client. During the introductory phase (option 1), the nurse usually engages in some social interaction to put the client at ease. During the working phase (option 2), the nurse helps the client to explore feelings and plan a program. During the termination phase (option 4), the nurse summarizes or reviews the process that took place. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 16-6.
3. **Answer:** 1 and 3. **Rationale:** Options 1 and 3 are listening behaviors; options 2, 4, and 5 are barriers to listening. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 16-4.

4. **Answer:** 1. **Rationale:** Respect is correct because the nurse is validating the client's feeling. It is not genuineness (option 2) because the nurse is giving information versus being genuine. Concreteness (option 3) is giving a specific example. The nurse is not confronting (option 4) but supporting through respect for the client's feelings. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 16-6.
5. **Answer:** 1, 3, 5. **Rationale:** These options reflect impairments to communication. Option 1 is a sensory deficit of deafness. Option 3 is a possible cognitive impairment, and option 5 is an example of a structural deficit. The nursing diagnosis altered verbal communication may *not* be useful when an individual's communication problems are caused by a psychiatric illness (option 2). If the communication issue is due to a problem coping, the diagnosis of fear or anxiety may be more appropriate (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 16-7.
6. **Answer:** 2 and 3. **Rationale:** Assessing possible visual or hearing problems allows the nurse to provide appropriate interventions (e.g., inserting hearing aid). Communicating what will be occurring at a stressful time helps the client feel more secure and can reduce anxiety. Option 1 is not the best answer as the client could say yes or no or nod the head and the nurse will not know if the client fully understands. It would be better to ask the client to tell you where he or she is. Option 4 is important to do; however, immediately after surgery is not the best time as the client may be in pain or groggy from the anesthesia. Option 5 is false reassurance because the nurse does not know if the client is going to feel better. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 16-4.
7. **Answer:** 3. **Rationale:** All the other options are forms of elderspeak. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 16-3.
8. **Answer:** 4. **Rationale:** Option 4 is a therapeutic technique using an open-ended question that allows the client to elaborate. The other options are barriers to communication. Option 1 is incorrect because the client did not ask about the abilities of the surgeon and the response does not focus on the client. Option 2 is changing the subject, and option 3 is giving advice. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 16-7.
9. **Answer:** 2. **Rationale:** Option 2 uses an "I" statement, which is assertive communication and is clear and direct. The message includes only the necessary information. Option 1 contains inflammatory language ("ineffective" and "you prescribed"). Options 3 and 4 do not provide the healthcare provider with specific information and could stimulate defensive behaviors. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 16-10.
10. **Answer:** 1. **Rationale:** It encourages the client to verbalize and choose the topic of the conversation. Option 2 is used when the nurse is unsure of the message and asks the client to repeat or restate the message. Option 3 is used to help a client differentiate the real from the unreal, and there is no information available to indicate this is a concern in this situation. Option 4 is used at the end of an interview or teaching session. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 16-4.

CHAPTER 17 Teaching

1. **Answer:** 2. **Rationale:** Options 1 and 3 are psychomotor, and 4 is under the cognitive domain. **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 17-3.
2. **Answer:** 3. **Rationale:** Options 1 and 2 are passive learning strategies. Learning is faster and retention better when the learner is actively involved. Option 4 promotes affective learning about adapting to a chronic health condition and is important. However, the question asks about learning diet information. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 17-9.
3. **Answer:** 2. **Rationale:** The client most ready to learn is experiencing or has recently experienced the least amount of stress or is the least preoccupied with other concerns. There will be no separation anxiety because the parents are present. The storybook may allow the child to learn information about the hospital and ask questions. The client in option 1 will be preoccupied by his illness. The client in option 3 is most likely still in pain. It would be better to wait until the pain is resolved. It would also be important to check if the client is too sleepy because pain medication can have that effect also. The client in option 4 may be too tired after his physical therapy treatment. This would need to be assessed. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 17-5.
4. **Answer:** 1. **Rationale:** Individuals learn in various ways, such as visually, group learning, auditory, and participatory. The individual knows how learning has occurred in the past. Option 2 is a component of the implementation phase of teaching, and the question is asking how to assess a client's style of learning. Options 3 and 4 involve others and it is best to ask the client. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 17-7.
5. **Answer:** 3. **Rationale:** Options 1 and 4 are not specific enough because they do not include the specific learning need. Option 2 is a wellness nursing diagnosis; the data would need to address that the client is seeking health information and why in order to be the correct answer. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 17-9.
6. **Answer:** 2, 3, and 5. **Rationale:** Options 2, 3, and 5 are open-ended questions that will give the client the opportunity to provide information that will help the nurse assess level of knowledge and subsequently provide and discuss needed information with the client. Options 1 and 4 are closed-ended (yes or no) questions. A "no" answer may cause a discussion but it will be difficult for the nurse to assess if it is the information the client really wants to know. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 17-7.
7. **Answer:** 1, 2, 3, and 4. **Rationale:** All of these statements could indicate a low literacy skill. The nurse will need to assess which teaching strategies will be most appropriate and will also need to carefully evaluate if the client has learned the skill and necessary information. Option 5 reflects an ability to read the material with a request for additional clarification. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 17-8.
8. **Answer:** 3. **Rationale:** All are important factors to assess. The priority, however, would be the potential economic factor because the medications can be very expensive and the client may not take them if he or she cannot afford them. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 17-7.
9. **Answer:** 3. **Rationale:** This option is the easiest for the nurse to evaluate. Option 1 is difficult to evaluate because "understand" is too vague. Option 2 refers more to an affective

outcome and the question is asking about a cognitive outcome. Option 4 is telling more about the husband than the client. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 17-13.

10. **Answer:** 2. **Rationale:** This is the only option that clearly reflects the teaching process, the evaluation method, and the response of the client indicating evidence of learning. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 17-14.

CHAPTER 18 Leading, Managing, and Delegating

1. **Answer:** 1. **Rationale:** This is a situation in which urgent decisions are needed, and one staff member provides instructions without input from others (autocratic). This is especially appropriate if the rest of the group is not functioning at an appropriate level. Option 2 would be found in shared governance structures when the risks are low and there is time for collaboration. Option 3 is most effective in groups with high levels of professional and personal maturity and where cooperation and coordination are not significant. Option 4 involves the rigid use of rules. Because managing casualties is a highly unpredictable activity, enforcement of rules is not appropriate. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 18-2.
2. **Answer:** 1. **Rationale:** In this situation, the manager needs to verify and clarify the client's statement with the assigned nurse before taking any direct action. Assigning another nurse to administer the client's medications (option 2) could be dangerous because it assumes the client is accurate in his statement. It is premature to review proper medication procedures with the nurse before knowing for certain that the procedure has not been followed (option 3). If the manager determines that there is disagreement about whether or not the medications have been given, it might be appropriate for the manager, nurse, and client to discuss the situation together (option 4) but certainly not before the manager has a private conversation about the situation with the nurse. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 18-7.
3. **Answer:** 2. **Rationale:** The manager is responsible for evaluating the staff (accountable) but has no authority to terminate staff who do not meet the standards or promote staff with outstanding performance. In option 1 the manager has authority to carry out the reduction, but is not accountable because the actions were delegated and not initiated independently. In option 3, the manager has only responsibility; in option 4, both authority and accountability. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 18-6.
4. **Answer:** 3. **Rationale:** A fresh postoperative client is, by definition, in a somewhat unstable condition and the nurse must assess and supervise this initial transfer. An AP should be able to perform the transfer safely with a new wheelchair; the scenario does not indicate that the wheelchair had special features (option 1) or that the client is an older adult. Age does not determine need for assistance and the AP should be able to transfer the older adult client (option 2). The task is simple and can be easily recalled safely after an absence (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 18-8.
5. **Answer:** 4. **Rationale:** Interaction between the two groups may lead to a compromise. Option 1: Although explaining the reasons for the desired change is useful, overemphasis on the rationale may not be useful since resistance is often more emotional than rational. Option 2: This situation does not meet the criteria for an autocratic leadership style. There is no urgency and the task primarily involves the staff. Option 3: If the manager is not solidly committed to the new proposal, it should not be introduced, because it will result in unnecessary disturbance. Option 4: The manager should be open to modification of the proposal if justified. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Planning. **Nursing Process:** Implementation. **Learning Outcome:** 18-10.
6. **Answer:** 2. **Rationale:** Managers are employees and have been given authority by the institution for which they work. The other options are characteristic of leaders more than managers. **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Planning. **Nursing Process:** N/A. **Learning Outcome:** 18-1.
7. **Answer:** 2, 3, and 5. **Rationale:** An effective leader is open to members' views on both sides of issues, orchestrates group activities, and is open to and solicits feedback on their style. Effective leaders use the style most natural to them rather than adopt another (option 1) and use a style appropriate to the situation and the groups as a whole, not varying for each member (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Planning. **Nursing Process:** Evaluation. **Learning Outcome:** 18-3.
8. **Answer:** 3. **Rationale:** Middle managers supervise first-level managers and serve as liaison between first- and upper-level managers. First-level managers supervise nonmanagerial staff (option 1) and report institutional changes to direct-care staff (option 2). Creating institutional goals and strategic plans is the responsibility of upper-level managers (option 4). **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Planning. **Nursing Process:** Evaluation. **Learning Outcome:** 18-4.
9. **Answer:** 4. **Rationale:** Evaluating outcomes and effectiveness is part of the coordinating function of management. **Cognitive Level:** Remembering. **Client Need:** Safe, Effective Care Planning. **Nursing Process:** N/A. **Learning Outcome:** 18-5.
10. **Answer:** 3. **Rationale:** In this situation, the AP was not given the right direction and communication—that the client was not permitted to be out of bed. AP commonly weigh clients so it was the right task and right person (options 1 and 2). Although supervision might have prevented the error, it was the nurse's responsibility to tell the AP of the client's mobility status and, if necessary, the proper way to weigh such a client (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Planning. **Nursing Process:** Evaluation. **Learning Outcome:** 18-9.

CHAPTER 19 Health Promotion

1. **Answer:** 3. **Rationale:** Holism implies consideration of all aspects of the client's life. Although arranging for home care (option 1), facilitating spirituality (option 2), and offering coping resources (option 4) may be appropriate, the nurse begins a holistic approach to care by examining, with the client, in what ways the illness influences the various segments of her life. The client is the best source of information regarding personal needs. Assessment should always precede intervention. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 19-1.
2. **Answer:** 3. **Rationale:** Learning about sleep will increase the older adult's well-being, which is the focus of health promotion. Prevention of falls (option 1) is health protection because the focus is avoiding injury. Learning about cardiovascular risk factors (option 2) relates to health protection and disease prevention. How to stop smoking (option 4) focuses on health protection and avoiding illness. **Cognitive Level:** Applying. **Client Need:** Health Promotion/Maintenance and Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 19-5.

3. **Answer:** 2. **Rationale:** Choices are often related to learned experiences, lifestyle, and values. The client obviously values the business more than physical health. When an individual feels strongly enough, a lower level need (rest) can be postponed until a higher level need (success, safety) is met. It is very likely that no one else can meet that need for him and the lower need must still be met eventually. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 19-3.
4. **Answer:** 3. **Rationale:** A client in this stage recognizes there is a problem, is seriously considering changing, actively gathers information, and verbalizes plans to change in the near future. Option 1 reflects the precontemplation stage in which the client denies there is a problem. Option 2 reflects the planning stage in which the client makes final plans to accomplish the change, and option 4 is the maintenance stage in which the client made the change and demonstrates the appropriate behavioral change. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 19-8.
5. **Answer:** 2. **Rationale:** Perceived self-efficacy is the confidence the client has for achieving the desired outcome. Option 1 is a client's perceptions about available time, inconvenience, expense, and difficulty performing the activity. Option 3 is the client's perceptions concerning the behaviors, beliefs, or attitudes of others. Option 4 refers to the client's perception of the environment and how it assists or detracts from the healthy behavior. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 19-7.
6. **Answer:** 2, 3, and 5. **Rationale:** The *Healthy People 2020* goals are broad based. Options 1 and 4 are specific methods to promote healthy behaviors and would be seen in the objectives for a *Healthy People 2020* topic area. **Cognitive Level:** Comprehending. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** N/A. **Learning Outcome:** 19-4.
7. **Answer:** 1. **Rationale:** Option 2 is a strategy for the contemplation stage, option 3 is a strategy for the preparation stage, and option 4 is a strategy for the maintenance stage. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 19-9.
8. **Answer:** 4. **Rationale:** Change is a complex process and a nurse should not give up or assume that the client does not want to change (option 1). Individuals often resist a tough approach because it can make them feel cornered. This approach may work for some individuals but not for everyone (option 2). The goal of teaching is to try to help the client become the expert as well (option 3). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 19-11.
9. **Answer:** 1. **Rationale:** The compensatory mechanism of increasing the heart rate is the body's way of trying to balance an ineffective cardiac output since the BP has decreased. Decompensation (option 2) occurs when the compensatory mechanism is ineffective. Self-regulation (option 3) refers to the homeostatic mechanisms that come into play automatically in the healthy individual. Equilibrium (option 4) is balance through adaptation to the environment. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 19-2.
10. **Answer:** 3. **Rationale:** Option 1 is a physiologic need. Option 2 is a love and belonging need, and option 4 is a safety and security need. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 19-3.

CHAPTER 20 Health, Wellness, and Illness

1. **Answer:** 3. **Rationale:** Frustration is an example of an emotion. The client who chooses healthy foods (option 1) represents the physical component, taking parenting classes enhances the intellectual component (option 2), and the bowling league (option 4) enhances both the physical and social components. **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 20-2.
2. **Answer:** 2. **Rationale:** The mother has taken on the sick role by expecting to be excused from her usual role responsibilities. The sick role states that individuals are not answerable for their illness, contrary to the obese client's perspective (option 1). In the sick role, the client tries to get better as opposed to the man who misses his physical therapy appointments (option 3). The older adult is not following the sick role expectation to rely on competent help (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion/Maintenance and Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 20-7.
3. **Answer:** 1. **Rationale:** The behavior is most representative of health promotion, which is the central focus of the health belief model. The clinical model focuses on relieving signs and symptoms of illness (option 2). The role performance model emphasizes social activities such as fulfilling a particular role (option 3). The agent–host–environment model focuses on predicting illness (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Analysis. **Learning Outcome:** 20-3.
4. **Answer:** 2, 3, and 4. **Rationale:** Significant evidence exists that a trusting relationship with the provider, effectiveness of the medication, and simple dosing regimen are important predictors of adherence to a medical regimen. Neither education nor sex has been shown to be a predictive factor (options 1 and 5). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 20-5.
5. **Answer:** 1. **Rationale:** Although not always practical, direct observation is the best method to measure adherence (for example, watching clients who are addicted to heroin actually take their methadone dose). Because lack of adherence may be life threatening or damaging to the client as well as others, waiting until the client displays illness and waiting until laboratory values reflect a lack of adherence are not the best methods (options 2 and 3). Client report or recall is not always accurate, even if the client believes he or she is telling the truth (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 20-5.
6. **Answer:** 4. **Rationale:** The actual term used to describe the diagnosis is less important because the client may have no frame of reference for it. That is not to say that the diagnosis is unimportant because clients may be familiar with common diagnoses such as heart disease or cancer and ascribe historical meaning to them. Ability to perform usual activities, culture, and availability of healthcare will all be strong influences on the client's definition of health or wellness (options 1, 2, and 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 20-1.
7. **Answer:** 4. **Rationale:** Genetics is an internal variable affecting health. Options 1, 2, and 3 are all external variables. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 20-4.
8. **Answer:** 2. **Rationale:** By definition, a chronic illness has no known cure, so the individual will always have it to some degree. Although acute illnesses may have severe symptoms,

many chronic illnesses also have severe symptoms (option 1). Although signs and symptoms of chronic illnesses may never go completely away, they can get better and worse at different times (option 3). Chronic illnesses can be treated, just not cured (option 4). **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 20-6.

9. **Answer:** 3, 5, 1, 4, and 2. **Rationale:** The proper sequence of Suchman's stages of illness are signs and symptoms appear, the client takes on the sick role, the client makes contact with medical care, the client takes on a dependent role, and the client goes into rehabilitation and recovery. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 20-8.
10. **Answer:** 1, 2, 3, and 5. **Rationale:** In the sick role, the woman would likely feel guilt and some anger but give up usual roles and accept help from others, and decrease social interactions. The only reaction that would be unlikely is that she would take on a job to pay expenses. This would be inconsistent with the sick role. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 20-9.

CHAPTER 21 Culturally Responsive Nursing Care

1. **Answer:** 3. **Rationale:** There is an ongoing shift in the U.S. population that includes a decreasing number of White individuals (formerly the majority population) and an increasing number of other cultural groups. The birth rate is actually decreasing (option 1); limited access to healthcare is a complex issue that is not the major factor here (option 2); and immigration has increased (option 4). **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** N/A. **Learning Outcome:** 21-3.
2. **Answer:** 2. **Rationale:** Cultural differences may result in various interpretations of a medical regime. Cultural responsiveness results in recognition of the right "not to fit." This is a standard of practice and should be initiated with all clients (option 1). Teaching or explaining the effects of lack of adherence would be more appropriate than warning (option 3). Asking an individual of the same culture to assist may be helpful after the nurse discusses the matter with the client (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** N/A. **Learning Outcome:** 21-10.
3. **Answer:** 3. **Rationale:** The nurse should indicate that he or she is open to diverse views and practices. Option 1 assumes the client follows this particular cultural practice, which may not be the case. The nurse should assess before intervening. It may be good to learn more about the culture (option 2), but that is not the best starting place to care for the client. Subcultures exist among all cultures. Reading books is helpful, but assessment of individual situations is the best approach. Option 4 reflects an incorrect approach to culturally appropriate care. The nurse needs to assess which customs and practices the individual client performs before drawing conclusions. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** N/A. **Learning Outcome:** 21-10.
4. **Answer:** 3. **Rationale:** Being culturally responsive implies that, within the delivered care, the nurse understands and attends to the total context of the client's situation, including awareness of immigration, stress factors, and cultural differences. Options 1 and 2 do not show that the nurse needs to respect the choices made by the clients. Option 4 shows bias or stereotyping. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** N/A. **Learning Outcome:** 21-4.
5. **Answer:** 3. **Rationale:** National cultural health goals include providing equal access to quality healthcare for everyone. It would be inappropriate for all cultures to receive the same care; care should be customized (option 1). The same life expectancy for all U.S. citizens is not realistic (option 2). Assimilation (option 4) is not an appropriate health goal because assimilation is a conscious effect. Therefore, it is not always possible and this may cause severe stress and anxiety. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 21-3.
6. **Answer:** 1. **Rationale:** Herbal teas are an example of a restoring health action. Prayer (option 2) and exercise (option 4) would be examples of maintaining actions, whereas wearing symbolic objects (option 3) is a protective action. **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 21-6.
7. **Answer:** 2. **Rationale:** Steam is a natural substance and would be compatible with folk healing preferences. Hospitalization and medications are typical Western medical strategies (options 1 and 3). A watch-and-wait approach (option 4) is not particularly associated with a folk healing perspective. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 21-5.
8. **Answer:** 1, 2, 3, and 6. **Rationale:** Technology skills (option 4) and intelligence (option 5) are individual, personal characteristics and less influenced by one's culture than valuing of older adults (option 1), gender roles (option 2), nonverbal communication (option 3), or diet (option 6). Culture may, however, influence how technologic skills (option 4) and intelligence (option 5) are viewed and valued. **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 21-5.
9. **Answer:** 4. **Rationale:** To gather assessment data regarding the client's heritage, nurses must explore clients' beliefs and practices. A good beginning would be to ask clients to indicate which items on the checklist apply to them. Physical examination (option 1) and medical history (option 2) may suggest some cultural affiliation but the nurse cannot assume that these findings show significant affiliation from the client's perspective. Blood analysis generally provides little data for a heritage assessment, although blood type and some immunologic or genetic data can be relevant (option 3). **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 21-9.
10. **Answer:** 2. **Rationale:** If an interpreter is not available at your agency, you must still meet the expectations of providing information in a way that allows the client to comprehend it. Providing written instructions, whether in English or the client's language, is insufficient since the client may not be able to read and remains unable to have questions answered (option 1). Family members should not be relied on to interpret medical information (option 3). Option 4 is not an appropriate action. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 21-7.

CHAPTER 22 Complementary and Alternative Healing Modalities

1. **Answer:** 3. **Rationale:** Although the effectiveness of alternative therapies is sometimes not scientifically established, many individuals report significant benefit from them for a wide variety of conditions. Alternative therapies often cost less, but this is not a primary consideration (option 1). Clients often seek alternative therapies because traditional therapies are ineffective, but this is not the primary difference (option 2). Both traditional and alternative therapies utilize products from nature (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** N/A. **Learning Outcome:** 22-1.
2. **Answer:** 1. **Rationale:** Spirituality gives us purpose and meaning in life; involves a relationship with oneself, others, and a higher power; and involves finding significant meaning in the entirety of life. Spirituality is a much broader concept than religion and religious services. Responsibility for life patterns is

a concept of humanism. **Cognitive Level:** Applying. **Client Need:** Psychological Integrity. **Nursing Process:** N/A. **Learning Outcome:** 22-9.

3. **Answer:** 2. **Rationale:** Healing environments are created when nurses empower clients to make healthy decisions. They are not dependent on technology (option 1) or primary care providers' orders (option 4). A safe physical environment is neither necessary nor sufficient for there to be a healing environment (option 3). **Cognitive Level:** Applying. **Client Need:** Health Promotion/Maintenance and Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 22-2.
4. **Answer:** 4. **Rationale:** Naturopathy focuses on the total individual. The primary focus is disease prevention. Naturopathy may be the best choice in decreasing disease rates by empowering and educating individuals about ways to stay healthy. Belief in a higher being is not a core principle. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** N/A. **Learning Outcome:** 22-5.
5. **Answer:** 2. **Rationale:** Qi is the flow of energy in the body that must be uninterrupted for an individual to be in a healthy state. All other imbalances may result from an imbalance in the flow of qi or flow of vital energy through specific anatomic points along the surface of the body (options 1, 3, and 4). **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** N/A. **Learning Outcome:** 22-7.
6. **Answer:** 2. **Rationale:** Thirty percent of current prescription drugs are derived from plants. Herbs and medications are similar in structure and therapeutic value (option 1). Some medications may be more powerful than herbs but not all are (option 3), and herbs tend to be less dangerous than medications (option 4). **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 22-4.
7. **Answer:** 1. **Rationale:** Serious interactions can occur between herbs and medications. It is acceptable that individuals choose herbs as a way to maintain health and treat minor disorders (option 2). Although the knowledge the nurse gains may be helpful, contributing to research is not the primary reason for assessing herb use (option 3). While we hope clients share important information with us, they also have free will about what they choose to share (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 22-10.
8. **Answer:** 4. **Rationale:** The oils in options 1, 2, and 3 will burn the skin if they are not diluted in a carrier oil. **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 22-10.
9. **Answer:** 1, 2, 4, and 5. **Rationale:** Massage is a way of communicating without words, including the caring intent of the provider. It provides mental and physical relaxation. Massage speeds the removal of metabolic waste products, allowing more oxygen and nutrients to reach the cells and tissues. It lowers blood pressure and slows the heart rate. Passive exercise from massage cannot strengthen muscles (option 3). **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 22-6.
10. **Answer:** 1. **Rationale:** There is no evidence that massage (option 2), herbs (option 3), or yoga (option 4) improves pregnancy rates, although relaxation and good physical conditioning are generally encouraged. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 22-10.

CHAPTER 23 Concepts of Growth and Development

1. **Answer:** 3. **Rationale:** The sequence of each stage of development is predictable, although the time of onset, the length of the stage, and the effects of each stage vary with the individual. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 23-2.
2. **Answer:** 4. **Rationale:** The study of growth (physical) and development (function and skills) is correct because the answer needs to have both components to be complete. Option 1 addresses only the growth aspects. Option 2 addresses only developmental aspects, and option 3 addresses only the environmental factors that might influence growth and development. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 23-1.
3. **Answer:** 3. **Rationale:** Toddlers typically demonstrate negative behavior and are hesitant around strangers, resisting close contact with those they do not know well. They do not have sophisticated language skills and often use crying or fussing to communicate. Older school-age children and adolescents are likely to cooperate without complaint in many health procedures (option 1). School-age children, engaged in the task of industry versus inferiority, display curiosity about how things work, asking many questions of nurses (option 2). Preschool-age children, who are in the fantasy, curiosity, and exploration stage, like to manipulate objects and play "pretend" (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 23-7.
4. **Answer:** 4. **Rationale:** Adolescents need to establish identity, which involves developing a more mature sense of independence and responsibility. Providing adolescents with schoolwork keeps them connected to peer groups and gives a sense of accomplishment. Also, it prevents clients from "worrying" about getting behind in school assignments. Interaction with peers is very important during this stage, but they are likely to be attending school during the day (option 1); an infant's sense of trust is reinforced if parents room-in, and older infants and toddlers experience less separation anxiety if parents are nearby (option 2); and preschool and school-age children would benefit from the distraction and social interaction of others in the recreation room (option 3). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 23-5.
5. **Answer:** 2. **Rationale:** The client is in Erikson's stage of integrity versus despair. Finding meaning and purpose in his life after retirement is a sign of achievement. His comments regarding visits to his family and being asked by friends to help with their projects indicate that he is actively involved and purposeful (options 1 and 4). His comment regarding needing medication for knee pain can be expected in many older adults, especially those who have been laborers or suffered injury when younger (option 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 23-5.
6. **Answer:** 2. **Rationale:** This stage includes the preadolescent period. The peer group increasingly influences behavior. Physical, cognitive, and social development increases and communication skills improve. One needs to allow time and energy for the school-age child to pursue hobbies and school activities and to recognize and support the child's achievement. Option 1 is a judgmental statement as this is not unusual and not indicative of problems in the home. It is good to be supportive of the school-age child; however, making her stay home with her family might cause anger and resentment (option 3). Option 4 is also a judgmental statement. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 23-8.
7. **Answer:** 2. **Rationale:** Erikson's late childhood stage focuses on initiative versus guilt. During this stage, the children are beginning to have the ability to evaluate their own behavior and

are learning the degree to which assertiveness and purpose influence the environment. Option 1 is incorrect because Fowler's focus is spiritual development. Both options 3 and 4 are names of adult theorists. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 23-7.

8. **Answer:** 1. **Rationale:** Piaget identifies this phase as the intuitive thought phase with significant behaviors as follows: egocentric thinking diminishes, thinks of one idea at a time, includes others in the environment, words express thoughts. Erikson identifies this developmental stage as industry versus inferiority, and the children are learning the degree to which assertiveness and purpose influence the environment. They begin to have the ability to evaluate their own behavior. Fowler identifies this stage as intuitive-projective, a combination of images and beliefs given by trusted others, mixed with the child's own experience and imagination. Therefore, the nurse knows that this child has a normal imagination and needs to explore and learn about this new piece of equipment in language appropriate to his age. For option 2, imagination is normal for this age group, and stating that he needs to be "a big boy" is counterproductive. Option 3 is incorrect because his language skills are developing and he needs to understand the world around him. Option 4 is incorrect because adding to his fears will only increase his anxiety level and decrease his trust in you as a nurse. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 23-11.
9. **Answer:** 1. **Rationale:** All the nursing actions listed here are appropriate, but attachment theory emphasizes the importance of parents being available to their child when the child is experiencing stress. The best action would be to encourage the mother to stay with her child as much as possible. Putting a picture of the mother in the crib (option 2) may provide some comfort, since by 15 months of age, children demonstrate object permanence and people permanence, so the child "knows" the mother will return. Holding and cuddling the child (option 3) may also provide comfort, but the child must trust the caregiver, and the nurse's other responsibilities may restrict the amount of time and when he or she can be with the child. Distraction (option 4) can temporarily refocus the child's attention, but it does not address the need for emotional and physical contact with the parent. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 23-10.
10. **Answer:** 2. **Rationale:** Although many young adults are choosing to live with their parents, often for economic reasons, option 2 raises concern, because it implies a degree of selfishness and lack of effort to establish independence. This may not be the case, however, and the nurse would need to gather more information before making any judgments. Twenty-five-year-olds, according to psychosocial development theory, have established a sense of self-identity, made a commitment to their community through work and the social group, and are engaged in intimate relationships. According to Erikson, they are in the stage of intimacy versus isolation, moving into the adult stage of generativity versus stagnation. From Havighurst's perspective, early adults are starting families of their own, managing a home, and taking on the responsibility of work and civic life. Avoiding a relationship and neglecting a career or lifestyle commitment are red flags for failure to achieve developmental milestones at this age. Engaging in healthy exercise (option 1) reflects a quality of self-identity for this individual. Option 3 suggests the client actively cooperates in his recovery and is able to focus on the future (wanting to recover from surgery). Option 4 indicates the client is part of a "congenial social group" (Havighurst). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 23-8.

CHAPTER 24 Promoting Health from Conception Through Adolescence

1. **Answer:** 4. **Rationale:** Providing opportunities for the parent to express worries and discuss facts about SIDS gives more control over the situation. The nurse can also provide the parent with information about the Back to Sleep campaign. Option 1: The highest incidence of SIDS occurs between 2 and 4 months of age, but it does occur in older infants. It is not the best response because it provides facts but does not address the parent's immediate concerns. Option 2: SIDS affects boys more than girls. However, this information is likely to increase anxiety and does not address the concerns of the parent. Option 3: There is no known cause of SIDS, although respiratory problems may be present in some infants. This response is insensitive to the needs of the parent. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 24-8.
2. **Answer:** 3. **Rationale:** Preschool-age children use fantasy and make-believe to learn about, understand, and master their environment, including their concepts of death. The child's conceptualization of death is consistent with her cognitive development. The response in option 1 negates the child's understanding and limits her ability to develop fuller understanding and adapt to the loss. Option 2 negates the child's attempts to understand and deal with the loss. Option 4 is incorrect because at 4 years of age, children can hear explanations such as "when people get old they will die," but these children do not have a firm grasp of the meaning of time and age, and probably will not understand. **Cognitive Level:** Applying. **Client Need:** Health Promotion/Maintenance and Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 24-6.
3. **Answer:** 1. **Rationale:** It is the responsibility of adults to supervise children constantly and closely when around water. Option 2, learning water safety and how to swim, is important and should be encouraged at an early age, but that still does not ensure a child's safety. Option 3 is incorrect because young children are at risk near any amount of water that can cover the nose and mouth. Option 4: Infants and toddlers can drown in a very small amount of water, even several inches in a bathtub or "kiddie pool." **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment and Health Promotion/Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 24-8.
4. **Answer:** 2. **Rationale:** School-age children acquire stereognosis, the ability to identify an unseen object simply by touch. Option 1: Birth weight triples by about 12 months. Children enter school age weighing about 45 pounds and gain about 5 to 7 pounds per year. Option 3: Significant physical change occurs during the school-age years. Option 4: Fat deposits do not normally appear until puberty. **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 24-1.
5. **Answer:** 1. **Rationale:** Increased fat deposits are normal as girls begin hormonal changes of puberty. During this stage of development, females become very sensitive about their appearance and need reassurance. Option 2: Puberty is a period when children become more self-conscious of their appearance. They need to be reassured that normal weight gain and body changes with fat deposits are to be expected. The nurse would need to perform further individual assessments before determining if a weight problem existed. Option 3: Regular strenuous exercise should be a part of the healthy adolescent's lifestyle, but its goal should be to provide energy and strength, not to control weight. Option 4: Dieting and efforts to lose weight can threaten the health of adolescents. This intervention lacks scientific evidence. Unless an actual or potential disease process exists, a balanced diet is most

appropriate. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 24-1.

6. **Answer:** 2. **Rationale:** Many newborn babies have a misshapen head because of the molding made possible by fontanels in the bone structure of the skull and overriding of the sutures. This asymmetry is usually corrected within the first 7 to 10 days. Option 1: The client is crying and upset; the nurse's response needs to be more sensitive and caring. Option 3: Educational materials are not appropriate for a client who is crying and emotionally upset. Option 4: The client is concerned about the misshapen head right now. The most appropriate intervention should focus on relieving the current emotional state. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 24-1.
7. **Answer:** 1. **Rationale:** Although toddlers like to explore the environment, they always need to have a significant individual nearby. Parents need to know that young children experience acute separation anxiety and that abandonment is their greatest fear. Option 2: This is normal toddler development. Option 3: The child is probably not old enough to perform manipulative-type strategies. Option 4: This is normal behavior for this age group. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 24-3.
8. **Answer:** 3. **Rationale:** The child can perform regular activities as long as the injured arm and the cast are not placed in jeopardy. Option 1: A competent nurse could answer this question. Option 2: A 5-year-old needs to be physically active. This would be more appropriate for health problems in which moving about could prevent healing or cause injury. Limiting a preschooler to only sitting activities is unrealistic. Option 4: Riding a bike and jumping rope could place the client at risk for injury. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 24-2.
9. **Answer:** 1. **Rationale:** During the phase of concrete operations, children change from egocentric interactions to cooperative interactions. They also develop an increased understanding of concepts that are associated with specific objects. They learn to add and subtract and understand cause-and-effect relationships. Option 2 action is indicative of the preconceptual phase—an egocentric approach that uses magical thinking. Option 3 action is indicative of the formal operations phase—reasoning is deductive and futuristic. Option 4 is indicative of physical growth. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 24-4.
10. **Answer:** 1. **Rationale:** Often the first noticeable sign of puberty in females is the appearance of the breast bud, although the appearance of hair along the labia may precede this. Option 2: The growth spurt in girls is between ages 10 and 14, but is too vague to be noticeable. Option 3: The eccrine glands are found over most of the body and produce sweat. The apocrine glands develop in the axillae, anal and genital areas, external auditory canals, and around the umbilicus and the areola of the breasts. Option 4: Mood swings are not as definitive as physical changes. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 24-2.

CHAPTER 25 Promoting Health in Young and Middle-Aged Adults

1. **Answer:** 3. **Rationale:** The average age for the onset of menopause in American women is 47 years. Therefore, there is nothing abnormal about ongoing menses in a 45-year-old woman, and gynecologic care is not warranted (option 1). As a woman nears menopause, ovulation may become irregular and difficult to predict. Conception remains a possibility, and the lack of predictable ovulation may actually increase the likelihood of unintended pregnancy (option 2). Many women have no negative symptoms during menopause, and the experience of menopause is highly culturally determined (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 25-2.
2. **Answer:** 2. **Rationale:** Generation X is characterized by both skepticism and resentment of people in authority (such as a nurse). Baby boomers tend to be interested in improving themselves, and health teaching may be viewed as self-improvement (option 1). Generation Y and Millennials are the same cohort, and are most likely to receive their health information from technologic sources, such as the internet (options 3 and 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 25-1.
3. **Answer:** 3. **Rationale:** Lung cancer is the most common cause of cancer death in women age 24 to 65 years. Breast cancer is common, but deaths related to breast cancer have declined (option 1). Lymphoma and colon cancer are significant diseases for both men and women (options 2 and 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 25-7.
4. **Answer:** 4. **Rationale:** Although HIV and syphilis may have more disastrous health effects, chlamydia is the most prevalent infectious disease in the United States. Gonorrhea is still common, and its prevalence may vary geographically, but chlamydia is more common and therefore the most likely contracted STI (option 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 25-9.
5. **Answer:** 2. **Rationale:** Kohlberg's initial work indicated that moral development was completed by adulthood, but more recent research has demonstrated that moral development continues throughout adulthood. Moral development refers to a decision-making process of right and wrong, and proceeds in a series of predictable stages (option 3). Moral development and spirituality are unrelated, and represent very different spheres of human thought and behavior (option 4). **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 25-5.
6. **Answer:** 2. **Rationale:** The middle-aged individual is generally attempting to relate to adult children and grandchildren as well as assisting aging parents. Hence, continuous efforts to meet the needs of others occur. Selecting a life partner is the developmental task for young adults. Reviewing one's life course is the task for older adulthood (option 3). Establishing a sense of self is usually achieved during adolescence (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 25-3.
7. **Answer:** 3. **Rationale:** Because individuals over 50 years of age tend to have multiple chronic illnesses as well as an aging immune system, the influenza vaccine is highly recommended. Influenza can lead to serious complications in older adults. The pneumococcal vaccine protects against the most common pathogens that cause pneumonia. The vaccine must be given every 10 years. Immunization for pertussis is only appropriate in children, and meningococcal vaccine is appropriate in adolescents and young adults living in congregate housing. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 25-9.
8. **Answer:** 1, 2, 3, and 5. **Rationale:** Hypertension (elevated blood pressure) forces the heart to work harder, resulting

in decreased function of the heart; the electrocardiogram assesses cardiac rhythm and rate; high cholesterol levels are directly related to a decrease in arterial size, which decreases circulation blood to the cardiac tissue; activity level (e.g., dyspnea on exertion) can indicate cardiovascular disease. While cardiac impairment may decrease sexual performance, which is important to assess, the others would have priority given the limitations for the screening program (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 25-9.

9. **Answer:** 1. **Rationale:** Asking the individual if they are afraid of someone at home, or if someone hurt them, is a critical step in a comprehensive assessment. Intimate partner violence is a serious problem for women and men of all ages, cultures, and socioeconomic levels. The nurse should suspect it in clients whose injuries are not consistent with the history they give. Referring the client to a shelter without completing a thorough assessment may lead to inappropriate care (option 2); the nursing process requires assessment before intervention. Collaboration with other healthcare professionals may be very helpful but an assessment needs to be done first (option 3). Documentation of the assessment does not directly address, reduce, or solve the concern (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 25-7.
10. **Answer:** 3. **Rationale:** Each of these activities indicates achievement of a developmental task, but the nurse must know which task is appropriate for the client's chronological age. Obtaining and decorating a place to live is an activity that establishes independence from parents, a task for young adults. Creating a scrapbook is an important strategy to enhance ego integrity, a developmental task for older adults (option 1). Working with philanthropic groups is a hallmark of generativity, a developmental task for those in midlife (option 2). Considering career paths is more appropriate to the identity task of adolescence (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 25-3.

CHAPTER 26 Promoting Health in Older Adults

1. **Answer:** 1, 3, and 4. **Rationale:** Grieving is a normal behavior after the death of a loved one, and the behaviors listed in options 1, 3, and 4 indicate signs of normal grieving. When grieving becomes extreme, and signs of self-neglect or alcohol or other substance abuse are obvious, ineffective coping may be a problem. The nurse needs to be attentive to the problem and be prepared to call on appropriate resources, if needed. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 26-11.
2. **Answer:** 3. **Rationale:** Because the hearing loss occurs in the ability to distinguish high-pitched tones, speaking in a low and distinctive voice tone is the most appropriate method of communicating with the clients. Hearing loss in the older adult includes a loss of the ability to discern higher frequencies, and speaking slowly at a particular volume is not the best way to communicate with the clients (option 1). The stem indicates the clients have noticeable hearing loss, but does not indicate the clients are deaf; large lettering is appropriate if the client has a visual problem (option 2); hearing aids are not usually effective when the problem is related to neural damage (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 26-8.
3. **Answer:** 2. **Rationale:** Reminiscence about past life events, doing a "life review" of past experiences, especially if they were positive, is considered to be a normal psychosocial activity of older adults. It helps them focus on past accomplishments and contributions to society, thus increasing their self-concept. If behavioral or significant memory problems had been noted, then a geriatric psychiatric consult would be appropriate, but not in this situation (option 1). Other social activities and conversations should certainly be encouraged, but not to the point of demeaning the importance of his life stories (options 3 and 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 26-12.
4. **Answer:** 4. **Rationale:** It is a myth regarding the aging process that most older adults are depressed. By relating that depression is not a normal part of aging, the nurse can further dialogue with the daughter. The older client's number of losses is less important than how she copes (option 1). A depressed affect may be the older adult's usual look (option 2). It is yet to be determined if in fact she is depressed (option 3). **Cognitive Level:** Remembering. **Client Need:** Safe and Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 26-15.
5. **Answer:** 3. **Rationale:** This option will provide the nurse with the most information for potential intervention. Options 1, 2, and 4 are incorrect because urinary incontinence is not normal and it is something the nurse should investigate. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 26-15.
6. **Answer:** 1. **Rationale:** The client has lost muscle strength. Strengthening exercises will improve his mobility and lessen the possibility of a fall. Option 2: Information indicates the client has difficulty rising from a seating position, not standing after he reaches the position; further assessment is needed before implementing this intervention. Option 3: Praise should come after the proper intervention is implemented and a plan is in place so that the praise is focused toward a goal to resolve the problem. Option 4 resolves the problem immediately but does nothing to resolve the underlying problem. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 26-8.
7. **Answer:** 4. **Rationale:** Sexual activity is possible for older adults although the responses are slower. The clients would need a health history and physical assessment of the cardiovascular system before drawing this conclusion (option 1). With the introduction of Viagra, older men are more able to perform than in the past (option 2). Older men's interest tends to decline, but it is not known whether it is related to impotence; apparently this older client is interested in sexual activity (option 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 26-16.
8. **Answer:** 3. **Rationale:** Presbyopia is loss of near vision related to aging. Option 1 is loss of hearing ability related to aging. Option 2 is dry mouth related to a decrease in saliva, and option 4 is a decrease in the motility of the esophagus related to aging. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 26-8.
9. **Answer:** 4. **Rationale:** This response reflects an understanding of the different stages of independence and control an older adult experiences when admitted to the hospital and the need for the nurse to assess the client's need for control and autonomy. After admission, the client willingly gives up autonomy to the hospital routine because the client wants to get better (option 4). As the client's health improves and progresses, he or she wants to increase autonomy (option 1). Before discharge the client is thinking about if he or she can go home (option 2). Option 3 is not realistic given the usual hospital routine. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 26-6.

10. **Answer:** 3. **Rationale:** The nurse treats the older woman with empathy. Saying the sister is dead may trigger agitation or an argument. It may start the grieving process all over again and be distressing for the woman (option 1). These responses should be avoided. It is more compassionate to focus on the woman's feelings, and encourage her to talk about her sister and remembered events. Long-term memory remains functional in many clients with dementia compared to short-term memory. By having her reminisce, the nurse can stimulate the woman's recall of events from a long time ago (option 3). It is deceptive to say the sister won't visit today or that the woman should wait to see if she does visit today (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 26-12.

CHAPTER 27 Promoting Family Health

1. **Answer:** 1. **Rationale:** Grandparents, aunts, and uncles are considered extended family members. Parents and spouse are considered immediate family members. Children who no longer live at home are considered immediate family members. Roommates and close family friends may be considered extended family members if grandparents, aunts, and uncles do not exist. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 27-2.
2. **Answer:** 4. **Rationale:** The data indicate that Mary is at the greatest risk of developing a health problem due to her stress of repeating a year of high school, many colds, drug use, and no support indicated beyond her family. Although Alice has a heart problem, she also has strong support medically and spiritually. Bill has asthma but no other risk factors are identified. Kim has back problems, is the mother of four children, and is married for the second time to an alcoholic and is also at risk, but not as great a risk as Mary. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Diagnosis. **Learning Outcome:** 27-5.
3. **Answer:** 1. **Rationale:** The health history of the client's current living partners is critical information since many illnesses are communicable or environmental. Giving this advice, the nurse also validates that family are whoever the client says they are. History of illness data of blood relatives is also extremely valuable and should always be included, whether or not the client lives with them. Neither the history nor the physical exam is more important than the other—both are necessary for a complete plan of care. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 27-4.
4. **Answer:** A visual representation of family members by gender, age, health status, and lines of relationships through the generations is referred to as a genogram. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 27-4.
5. **Answer:** 1, 2, and 4. **Rationale:** It is essential for the nurse to determine the duration of the illness, the meaning of the illness to the family and its significance to family systems, and the financial impact of the illness in order to completely assess the impact of the illness on the family as a whole. Duration of the illness will determine the degree of disruption and adaptation required. These factors affect the members of the family in addition to the ill client. Option 3: Coping mechanisms used by other families with similar illnesses may not be relevant because families vary greatly in their makeup and function patterns. Option 5: Knowing the incidence of the illness in the community at large is an important factor for the community health nurse in exploring epidemiologic issues such as prevention strategies and public health policies but is not as relevant for assisting the particular family. **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 27-6.
6. **Answer:** 1. **Rationale:** Presenting to the clinic indicates the family is probably ready to face the health challenges caused by the previous activities. There is no evidence that the adult child or parent is experiencing impaired coping (option 2). Alteration in parenting applies when the parent is unable to care for a child rather than the reverse. Although some strain must be experienced by the child, evidence does not indicate that impairment in caregiver role is the most important aspect of the situation. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Diagnosis. **Learning Outcome:** 27-6.
7. **Answer:** 3. **Rationale:** Establishing trust allows for effective communication and confirms that there is mutual commitment to the goals. Meetings with the family as a group should be goal oriented. A trusting relationship is important for communication as well as accepting and implementing a plan. While considering the cost of healthcare is important, it does not take priority over a trusting relationship with the nurse. A detailed history and examination of each family member is relevant but family members or the family as a whole will need to trust the nurse before providing the information. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 27-6.
8. **Answer:** 4. **Rationale:** The focus of activity on personal purposes does not promote effective family functioning. A family system that functions efficiently focuses primarily on purposes involving the total system, allows input from the outside, has personal boundaries that are well defined, and has interdependent family members. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 27-3.
9. **Answer:** 2. **Rationale:** A family should provide an environment that supports the growth of the individual members. It is neither possible nor appropriate for the family to try to provide everything each member wants (option 1), nor that members are accepted into society (option 3). Although the family protects its members, a healthy family will share and use appropriate resources with the broader community (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 27-1.
10. **Answer:** 3. **Rationale:** A family with sudden loss of income and health insurance is at the greatest risk for developing a health problem because it may no longer be able to afford preventive or therapeutic care. Having family members in many different developmental stages may cause stressors but this is not of high priority (option 1). The history of adult-onset diabetes on the 42-year-old father's side and the sedentary lifestyle should be addressed but will not likely cause immediate health problems (options 2 and 4). **Cognitive Level:** Analyzing. **Client Need:** Health promotion and maintenance. **Nursing Process:** Planning. **Learning Outcome:** 27-5.

CHAPTER 28 Vital Signs

1. **Answer:** 2. **Rationale:** Although the temperature is slightly lower than expected for the morning, it would be best to determine the client's previous temperature range next. This may be a normal range for this client. Depending on that finding, the nurse might want to retake it in a few minutes—no need to wait 15 minutes (option 1) or use another thermometer to see if the initial thermometer was functioning properly (option 3). Chart after determining that the temperature has been measured properly (option 4). **Cognitive Level:** Applying. **Client Need:** Health Maintenance and Promotion. **Nursing Process:** Assessment. **Learning Outcome:** 28-4.

2. **Answer:** 3. **Rationale:** The apical rate would confirm the rate and determine the actual cardiac rhythm for a client with an abnormal rhythm; a radial pulse would reveal only the heart rate and suggest an arrhythmia. For clients in shock, use the carotid or femoral pulse (option 1). The radial pulse is adequate for determining a change in the orthostatic heart rate (option 2). The radial pulse is appropriate for routine postoperative vital sign checks for clients with regular pulses (option 4). **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 28-5.
3. **Answer:** 4. **Rationale:** Since the client's needs are always considered first, the measurement should be delayed unless the client is in distress or there are other urgent reasons. Option 1: Respirations should be measured for 30 seconds to 1 minute and are affected by talking. Option 2: There needs to be an important reason for interrupting the client. Option 3: It is inappropriate to wait and listen to the client's conversation. **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 28-3d.
4. **Answer:** 2. **Rationale:** If the cuff is inflated to about 30 mmHg over previous systolic pressure, that would be 168. To ensure that the diastolic has been determined, the cuff should be released slowly until the mid-60s mmHg (and then completely) for someone with a previous reading of 74. The cuff should be deflated at a rate of 2 to 3 mm per second. Thus, a range of 90 mmHg will require 30 to 45 seconds. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 28-3e.
5. **Answer:** 1. **Rationale:** Vital signs measurement may be assigned to AP if the client is in stable condition, the findings are expected to be predictable, and the technique requires no modification. Only the preoperative client meets these requirements. In addition, AP are not delegated to take apical pulse measurements for the client with an irregular pulse as would be the case with the client newly started on antiarrhythmic medication (option 3). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 28-8.
6. **Answer:** 3, 4, and 5. **Rationale:** For this client, the nurse could take an axillary, tympanic, or temporal artery temperature. Due to the facial drooping and difficulty swallowing, the oral route is not recommended (option 1). Although the rectal route could be used, it would require unnecessary moving and positioning of a client who cannot assist, and it would not provide a significant advantage over the other routes (option 2). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 28-1.
7. **Answer:** 4. **Rationale:** The posterior tibial and pedal pulses in the foot are considered peripheral and at least one of them should be palpable in normal individuals. Option 1: A bounding radial pulse is more indicative that perfusion exists. Options 2 and 3: Apical and carotid pulses are central and not peripheral. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Diagnosing. **Learning Outcome:** 28-9.
8. **Answer:** 3. **Rationale:** Dyspnea, difficult or labored breathing, is commonly related to inadequate oxygenation. Therefore, the client is likely to experience shortness of breath, that is, a sense that none of the breaths provide enough oxygen and an immediate second breath is needed. Option 1: Shallow respirations are seen in tachypnea (rapid breathing). Option 2: Wheezing is a high-pitched breathing sound that may or may not occur with dyspnea. Option 4: The medical term for coughing up blood is hemoptysis and is unrelated to dyspnea. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 28-7.
9. **Answer:** This blood pressure should be recorded as 180/105/95 mmHg using the systolic/1st diastolic/2nd diastolic convention. **Rationale:** Phase 1 first sound is a clear tapping when deflation of the cuff begins. Phase 2 has a muffled, swishing sound. In phase 3, blood is flowing freely via an increasingly open artery; sounds are more crisp and more intense but softer than phase 1. Phase 4 sounds become muffled and have a soft blowing quality. In phase 5 the last sound is heard followed by silence. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 28-9.
10. **Answer:** 4. **Rationale:** The SpO2 in this case is 97%. Option 1 indicates the systolic blood pressure of 121 mmHg, option 2 the mean arterial pressure of 95 mmHg, option 3 the pulse of 87 beats/min, and option 5 the diastolic blood pressure of 84 mmHg. In addition, the client's temperature is shown. **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 28-3f.

CHAPTER 29 Health Assessment

1. **Answer:** 2. **Rationale:** Resonance is a normal sound over the lung. Tympany would be heard over the stomach (air filled) (option 1), hyperresonance is never a normal finding (option 3), and dullness would be heard below (not above) the 10th intercostal space (option 4). **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcomes:** 29-3; 29-4k.
2. **Answer:** 4. **Rationale:** The client should sit for examination of the head and neck. For palpation of the abdomen (option 1), genitals (option 2), and breast (option 3), the client should be supine. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 29-2.
3. **Answer:** 1. **Rationale:** A bruit suggests abnormal turbulence in the aorta, and the primary care provider must be notified. For absence of bowel sounds to be considered abnormal, they must be silent for 3 to 5 minutes (option 2). Continuous bowel sounds are normally heard over the ileocecal valve following meals (option 3). Bowel sounds are more commonly irregular than they are regular (option 4). **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcomes:** 29-3; 29-4o; 29-8.
4. **Answer:** 1. **Rationale:** If a pedal pulse, which is more distal than the popliteal, is present, then adequate arterial circulation to the leg is present even though the popliteal artery has not been located. Presence of a femoral pulse would not provide confirmation that arterial flow exists below that point (option 2). Taking a thigh BP requires locating the popliteal pulse (option 3). Because the purpose of finding the popliteal pulse is to provide information about arterial circulation to the leg, checking the distal pulse before requesting assistance from another nurse is appropriate (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcomes:** 29-3; 29-4m.
5. **Answer:** 2. **Rationale:** Visual acuity often lessens with age. Facial hair is likely to become coarser, not finer (option 1). The sense of smell becomes less, rather than more acute (option 3). The respiratory rate and rhythm is regular at rest (option 4). However, both may change quickly with activity and be slow to return to the resting level. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluating. **Learning Outcome:** 29-3.
6. Answers include color, turgor, temperature, moisture, lesions, odor, and edema. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 29-4b.

7. **Answer:** 3. **Rationale:** Recent memory includes events of the current day. Recalling a series of numbers tests immediate recall (option 1). Recalling childhood events tests remote (long-term) memory (option 2), and subtracting backward from 100 tests attention span and calculation skills (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcomes:** 29-3; 29-4q.
8. **Answer:** 4. **Rationale:** If the client can only read the first three lines, vision is impaired and could lead to falls or other injuries. This impaired vision is not related to ability to read (option 1) or memory (option 2). Myopia (option 3) is a medical diagnosis. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Diagnosing. **Learning Outcomes:** 29-3; 29-8.
9. **Answer:** 3. **Rationale:** Use the pads of two fingers and a gentle rotating motion over the nodes. None of the other options is proper palpation of lymph nodes. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 29-2.
10. **Answer**: Of the terms listed, only equal, symmetrical, and firm are normal findings. Atrophied, flaccid, contractured, hypertrophied, crepitation, spastic, and tremor are abnormal findings. Review the terms in the glossary to go over their meanings. **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcomes:** 29-4p; 29-8.

CHAPTER 30 Pain Assessment and Management

1. **Answer:** 3. **Rationale:** During the transduction phase, tissue injury triggers the release of biochemical mediators such as prostaglandin. Ibuprofen works by blocking the production of prostaglandin. The adjuvant medication in option 1 would affect the modulation phase because adjuvants inhibit the reuptake of norepinephrine and serotonin, which increases the modulation phase that helps inhibit painful ascending stimuli. Opioids block the release of neurotransmitters, particularly substance P, which stops the pain at the spinal level that occurs during the transmission phase (option 2). Distraction is best used during the perception phase when the client becomes conscious of the pain. Distraction (e.g., music, guided imagery, TV) can help direct the client's attention away from the pain (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 30-2.
2. **Answer:** 2. **Rationale:** In a postoperative client, it is important to assess pain intensity frequently to manage the acute pain experience. Option 1: The most pain a client is willing to tolerate before taking action can be discussed with the client after the pain intensity has been assessed. Option 3, location of pain, is important, but it is not the priority. Option 4: Pain history is important but not for a client in acute pain. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 30-4.
3. **Answer:** 4. **Rationale:** A rating of 7 is considered severe and demands immediate attention. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 30-4.
4. **Answer:** 1. **Rationale:** This indicates an increasing level of sedation, which can be an early sign of impending respiratory depression. Option 2 is normal. Option 3 can indicate increasing sedation; however, option 1 describes a higher level of sedation and an intervention such as notifying the primary care provider. Option 4 indicates pain management that may be tolerable for the client. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 30-6.
5. **Answer:** 4. **Rationale:** The client's perception and intensity rating of his pain is the most important even though other signs may suggest he is not having pain. His pain rating along with the vital signs objective data warrants a higher dose of the as-needed (prn) morphine. With option 1, you would be undermedicating the client based on his perception or rating of the pain. Option 2: Research shows that few clients become addicted when receiving opioids for acute pain over a short period of time, plus there are no signs of addiction. Based on the data, this answer would also lead to the client being undermedicated. Option 3 does not address the intensity level and would lead to distrust by the client. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 30-6.
6. **Answer:** 4. **Rationale:** Options 2 and 3 are subcategories of physiologic pain (option 1). A clue to the answer is that the client has diabetes, which often leads to diabetic peripheral neuropathy. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 30-1.
7. **Answer:** 1, 4, and 5. **Rationale:** NSAIDs can cause the side effect of GI bleeding. Clients should be taught to take NSAIDs with food and a full glass of water. Finding out how often the client takes the NSAID can help assess the likelihood of side effects occurring. Options 2 and 3 do not relate to NSAIDs. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 30-10.
8. **Answer:** 2. **Rationale:** The words *pain* and *complain* may have emotional or sociocultural meanings (options 1 and 4). It is better to ask clients if they are having any discomfort—they can then elaborate in their own words. Option 3 is too general and expects clients to report their pain without being asked. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 30-4.
9. **Answer:** 3 and 5. **Rationale:** Older clients may deny pain because it may indicate a worsening of their condition that may threaten their independence. Older adults may use words other than *pain*. Although many perceive pain as a natural outcome of aging, it is not a natural part of aging (option 1). Pain perception may decrease (option 2) and opioids can be used with careful monitoring by the nurse (option 4). **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 30-6.
10. **Answer:** 1. **Rationale:** Based on the information provided, the nurse needs to determine the client's understanding of the effects of pain on recovery and if the client has misconceptions about pain. The signs and symptoms do not support option 2. Options 3 and 4 could be true, but the priority is option 1. Movement enhances respiratory, cardiovascular, and GI recovery from general anesthesia and the outcomes associated with a surgical procedure. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 30-5.

CHAPTER 31 Asepsis and Infection Prevention

1. **Answer:** 2. **Rationale:** Blocking the movement of the organism from the reservoir will succeed in preventing the infection of any other individuals. Since the carrier individual is the reservoir and the condition is chronic, it is not possible to eliminate the reservoir (option 1). Blocking the entry into a host (option 3) or decreasing the susceptibility of the host (option 4) will be effective for only that one single individual and, thus, is not as effective as blocking exit from the reservoir. **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 31-9.
2. **Answer:** 1. **Rationale:** Since the hands are frequently in contact with clients and equipment, they are the most obvious

source of transmission. Regular and routine hand hygiene is the most effective way to prevent movement of potentially infective materials. PPE (gloves and masks) is indicated for situations requiring SP (option 2). Isolation precautions are used for clients with known communicable diseases (option 3). Routine use of antibiotics is not effective and can be harmful due to the incidence of superinfection and development of resistant organisms (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 31-8.

3. **Answer:** 3. **Rationale:** SP include all aspects of contact precautions with the exception of placing the client in a private room. A mask is indicated when working over a sterile wound rather than an infected one (option 1). Disposable food trays are not necessary for clients with infected wounds unlikely to contaminate the client's hands (option 2). Sterile technique (surgical asepsis) is not indicated for all contact with the client (option 4). The nurse would utilize clean technique when dressing the wound to prevent introduction of additional microbes. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 31-10.
4. **Answer:** 1. **Rationale:** Unless overly contaminated by material that has splashed in the nurse's face and cannot be effectively rinsed off, goggles may be worn repeatedly (option 1). Since gowns are at high risk for contamination, they should be used only once and then discarded or washed (option 2). Surgical masks (option 3) and gloves (option 4) are never washed or reused. **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 31-11b.
5. **Answer:** 4. **Rationale:** It should not be necessary to unroll this small edge of the cuff. The most important consideration is the sterility of the fingers and hand that will be used to perform the sterile procedure. The rolled-under portion is now contaminated and should not be unrolled by the nurse or colleague since it would then touch the remaining sterile portion of the glove (option 3). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 31-11d.
6. **Answer:** 1, 2, 3, 4, and 5. **Rationale:** Proper use of alcohol-based products includes following these steps: Apply a palmful of product into a cupped hand—enough to cover all surfaces of both hands (option 1); rub palms together (option 2); interlace fingers palm to palm (option 3); rub palms against back of hands (option 4); and rub all surfaces of each finger with opposite hand (option 5); continue until product is dry—about 20 to 30 seconds, not 10 to 15 seconds as stated incorrectly in option 6. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 31-11a.
7. **Answer:** Because a malnourished client with a wound is less able to resist an infection, potential for infection is the most likely nursing diagnosis. Others may include pain or altered nutrition but they are less focused on the immediate health risk. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Diagnosing. **Learning Outcome:** 31-7.
8. **Answer:** 2. **Rationale:** Raw foods touched by human hands can carry significant infectious organisms and must be washed or peeled. Antimicrobial soap is not indicated for regular use and may lead to resistant organisms. Hand hygiene should occur as needed. Hot water can dry and harm skin, increasing the risk of infection (option 1). Clients should learn all the signs of inflammation and infection (e.g., redness, swelling, pain, heat) and not rely on the presence of pus to indicate this (option 3). Individuals should not share washcloths or towels (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcomes:** 31-8; 31-5.
9. **Answer:** 1. **Rationale:** Sterile objects are considered unsterile if placed lower than the waist. Only area 1 in this situation would be considered sterile. Above the neck, higher than 2 inches above the elbow, below the waist or table, and the back are all considered unsterile. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcomes:** 31-1; 31-11c.
10. **Answer:** 3. **Rationale:** All items within 1 inch of the edge of the sterile field are considered contaminated because the edge of the field is in contact with unsterile areas. When hands are ungloved, forceps tips are to be held downward to prevent fluid from becoming contaminated by the hands and then returned to the sterile field (option 1). Fields should be established immediately before use to prevent accidental contamination when not observed closely (option 2). Reaching over a sterile field increases the chances of dropping an unsterile item onto or touching the sterile field (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 31-11c.

CHAPTER 32 Safety

1. **Answer:** 3. **Rationale:** In the event of a fire, the nurse's priority responsibility is to rescue or protect the clients under his or her care. The next priorities are to report or alert the fire department, contain or confine the fire, and extinguish the fire. **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 32-5.
2. **Answer:** 1. **Rationale:** When educating a group of young to middle-aged adults on safety, it is important to instruct them on the leading cause of injuries in this group. The leading cause of injuries in this group is related to automobile use and becoming distracted while texting and using email. Option 2 is the leading cause for school-age children. Option 3 is the leading cause for older adults, and option 4 relates to adolescents. **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 32-4.
3. **Answer:** 3. **Rationale:** The placement of the bedside commode next to his bed will assist in decreasing the number of steps he is required to ambulate. This will assist in protecting him from injury due to falls. Option 1: Leaving the light on would assist the client in locating the bathroom but would not reduce the risk of fall when rushing to the bathroom. Option 2: The nurse cannot withhold a client's medication without consulting with the primary care provider. Option 4: If the client has orders to be up with assistance and the side rails are up, he is at risk for falls as well as falling from a greater distance. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 32-6.
4. **Answer:** 3. **Rationale:** A home that was built prior to 1978 has lead-based paint. The ingestion of lead-based paint chips places that child at risk for elevated serum lead levels and neurologic deficits. The most appropriate nursing diagnosis for this child is potential for poisoning. Option 1: The risk for suffocation is greater in infants and is not related to a home with lead-based paint. Options 2 and 4 are not related to lead-based paint. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Nursing Diagnosis. **Learning Outcome:** 32-5.
5. **Answer:** 4. **Rationale:** Option 4 is an intervention that can allow the client to feel independent and also alert the nursing staff when the client needs assistance. It is the most realistic answer that promotes client safety. Option 1 can increase agitation and confusion and removes the client's independence. Option 2 would help but transfers the responsibility to the

family member. Option 3 is inappropriate because the client could fall during the unobserved interval and it is not a realistic answer for the nurse. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcomes:** 32-6; 32-11a.

6. **Answer:** 2 and 5. **Rationale:** Options 2 and 5 are measures needed to keep the client safe in the event of another seizure. Option 1 is incorrect because the current nursing literature states to not put anything in the client's mouth during a seizure. Options 3 and 4 are more relevant after the cause of the seizure is known. Seizures are not all classified as epilepsy. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcomes:** 32-7; 32-11b.
7. **Answer:** 4. **Rationale:** Placing the bed in the lowest position results in a client falling the shortest distance. The client is least likely to fall when getting out of a bed that is at an appropriate height. Option 1 can cause a fall with injury because the client may fall from a higher distance when trying to get over the rail. Also, all side rails up is considered a restraint. Option 2 is important to do as certain medications can increase the risk of falling; however, this is not the best answer because it is not applicable to all clients. Option 3 helps the nurse assess a client's risk for falling but would not prevent injury. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 32-6.
8. **Answer:** 1, 2, 3, and 5. **Rationale:** These four options are alternatives to restraints and it is necessary for the nurse to attempt alternative options before making the decision to call the healthcare provider for an order for restraints (option 4). Orienting the client and explaining the IV device may help depending on the level of confusion and is an intervention for confused clients. Covering up or disguising the device may help by eliminating the strange distraction, and a mitt is considered an alternative as long as it is not tied to the bed and the client can remove it if desired. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcomes:** 32-8; 32-11c.
9. **Answer:** 3. **Rationale:** Suicide and homicide are two leading causes of death among teenagers. Adolescent males commit suicide at a higher rate than adolescent females. Options 1 and 2 are true; however, neither would be as high a priority as preventing suicide. Option 4 is not true. A driver's education course does not ensure safe practice. **Cognitive Level:** Analysis. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 32-5.
10. **Answer:** 1, 3, 4, and 5. **Rationale:** Standards require documentation of the necessity for restraints. The implementation of range-of-motion exercises prevents joint stiffness and pain from disuse. Orienting the client helps the nurse determine the necessity of the restraint. Option 2 is inappropriate because it may cause injury if the side rail is lowered without untying the restraint. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcomes:** 32-8; 32-11c.

CHAPTER 33 Hygiene

1. **Answer:** 3. **Rationale:** The client fits the descriptors for a semidependent functional level (see Table 33.2). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 33-3.
2. **Answer:** 3. **Rationale:** The client will be positioned in a side-lying position with the head of the bed lowered because the client is at risk for aspiration. The absence of the gag reflex lets the nurse know that the client has no natural defense (cough) and is at a higher risk for aspiration. All other answers are assessments more appropriate prior to bathing the client. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 33-4.
3. **Answer:** 2. **Rationale:** A lotion will help moisten the skin. Perfumed lotions contain alcohol, which is drying to the skin. Soaking the feet for a long time or frequently also causes dry skin (option 1). Applying foot powder is appropriate to prevent or control unpleasant foot odor (option 3). Elastic stockings may decrease circulation (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 33-13c.
4. **Answer:** 1. **Rationale:** Turn off the hearing aid. Option 2 is incorrect because an in-the-ear hearing aid is cleaned with a damp cloth. Option 3 is incorrect; make sure the volume is turned all the way down because a too loud volume is distressing. Check that the battery is in the hearing aid; do not remove the batteries (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 33-13g.
5. **Answer:** 4. **Rationale:** Both the placement of the linens for a surgical bed and placing the bed in a high position facilitate the client's transfer from a stretcher into the bed. The linens for a closed bed are drawn up to the top of the bed and under the pillows (option 3). **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 33-12.
6. **Answer:** 1, 2, and 4. **Rationale:** Moving quickly may agitate the client (option 3). Protesting, screaming, and crying are not normal (option 5). Stop the bath and approach again later. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 33-8.
7. **Answer:** 4. **Rationale:** It is important to retract the foreskin to remove the smegma that collects under the foreskin and can cause bacterial growth. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 33-1.
8. **Answer:** 1, 3, and 5. **Rationale:** The developmental level warrants supervision. If the bottle is given during naps or bedtime, the solution has continuous contact with the toddler's teeth. The first visit to the dentist should occur between the ages of 2 and 3 (option 2). More than 50% of older adults have their own teeth (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 33-4.
9. **Answer:** 2. **Rationale:** The client needs to avoid walking barefoot because that could cause injury that may result in an infection. Also, neurologic impairment is likely as a result of the diabetes, which may result in decreased sensation. The client would be unaware of an injury. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 33-4.
10. **Answer:** 1. **Rationale:** Fowler's is a semi-sitting position that should ease the client's breathing. The head of the bed (HOB) in semi-Fowler's is lower (option 2). The HOB is lowered in the Trendelenburg position (option 3). Although the HOB is raised in the reverse Trendelenburg position, it is a straight tilt and may not be as comfortable as Fowler's (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 33-11.

CHAPTER 34 Diagnostic Testing

1. **Answer:** 2. **Rationale:** Option 2 is very low and can lead to death. The client's red blood cells participate in oxygenation. Options 1, 3, and 4 are within normal range and should not be reported to the primary care provider. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 34-3.

2. **Answer:** 3. **Rationale:** Option 3 is the most important nursing measure. This will inform the staff that the client is on a 24-hour urine collection. Option 1 is not appropriate since the first voided specimen is to be discarded. Option 2 is not an appropriate nursing measure since the specimen container is clean not sterile, and one container is needed—not individual containers. Option 4 is inappropriate because some 24-hour urine collections do not require refrigeration. **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 34-6.
3. **Answer:** 2. **Rationale:** A KUB is an x-ray of the kidneys, ureters, and bladder. This does not require direct visualization. Option 1 is an IVP, an intravenous pyelogram, which requires the injection of a contrast media. Option 3 is a retrograde pyelography, which requires the injection of a contrast media. Option 4 is a cystoscopy, which uses a lighted instrument (cystoscope) inserted through the urethra, resulting in direct visualization. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 34-8.
4. **Answer:** 4. **Rationale:** This type of nuclear scan demonstrates the ability of tissues to absorb the chemical to indicate the physiology and function of an organ. Option 1 is an invasive procedure that focuses on blood flow through an organ. Options 2 and 3 provide information about density of tissue to help distinguish between normal and abnormal tissue of an organ. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 34-9.
5. **Answer:** 3. **Rationale:** Bone marrow aspiration includes deep penetration into soft tissue and large bones such as the sternum and iliac crest. This penetration can result in bleeding. The client should be observed for bleeding in the days following the procedure. Option 1 is a nursing action during a liver biopsy. Option 2 is a nursing action for a thoracentesis, and option 4 is a nursing action for a lumbar puncture. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 34-10.
6. **Answer:** 1 and 4. **Rationale:** ALT is an enzyme that contributes to protein and carbohydrate metabolism. An increase in the enzyme indicates damage to the liver. The liver contributes to the metabolism of protein, which results in the production of ammonia. If the liver is damaged, the ammonia level is increased. Options 2, 3, and 5 (myoglobin, cholesterol, and BNP) are relevant for heart disease. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 34-2.
7. **Answer:** 3. **Rationale:** A glycosylated hemoglobin will indicate the glucose levels for a period of time, which is indicated by the nurse practitioner. Options 1 and 2 will provide information about the current blood glucose, not the past history. Option 4 is used to assess for liver disease. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 34-2.
8. **Answer:** 2, 3, and 5. **Rationale:** The nurse should obtain the stool specimen from two different areas of the stool. The nurse should observe for a blue color change, which is indicative of a positive result. The nurse should assess for the ingestion of vitamin C by the client because it is contraindicated for 3 days prior to taking the specimen. Option 1 is incorrect since the reagent is placed on the specimen after it is applied to the testing card. Option 4 is incorrect because a pink color would be considered negative and does not require verification. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 34-5.
9. **Answer:** 2. **Rationale:** The puncture site is usually on the posterior chest. The client should be positioned leaning forward. This will allow the ribs to separate for exposure of the site. Option 1 is incorrect. The client should not be placed in the Trendelenburg position because the site would not be exposed. Option 3 is incorrect since changes in vital signs do not routinely occur with this procedure. Option 4 is incorrect. The client does not need to be medicated for pain with this procedure. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 34-10.
10. **Answer:** 2, 4, and 5. **Rationale:** The sputum specimen should be sent immediately to the laboratory. The client should be provided mouth care before and after the specimen is collected. The sputum specimen should be collected for three consecutive days. Option 1 is incorrect because the sputum specimen is collected in the morning not in the evening. Option 3 is incorrect because the term *spit* indicates that saliva is being examined. The client needs to cough up or expectorate mucus or sputum. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 34-7.

CHAPTER 35 Medication Administration

1. **Answer:** 2. **Rationale:** If there is any doubt, the medication administration process should be interrupted until the question is clarified. Listen to the client. Find out any other information the client may have about that certain medication. For example, does he know the dosage of the medication taken at home? Do not administer the medication (option 1). Inform the client that you will check the chart first. Review the chart to make sure there is no discrepancy between the physician's order and the MAR. Review the physician's progress notes because the medication may have been increased or reduced as part of the treatment plan (option 3). Check with the pharmacist because sometimes a pill may be a different color or shape based on the pharmaceutical company. Do not leave medications at the bedside. Medications should never be left unattended (option 4). Inform the client of your findings. The client will appreciate that you took the time to make sure that he received the correct medication. While it takes time to check out the client's statement, you will be glad that you avoided a potential medication error. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-11.
2. **Answer:** 4. **Rationale:** Options 1, 2, and 3 are written appropriately. Option 4 is incorrect because the dosage is missing from this order. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 35-6.
3. **Answer:** 1, 3, and 5. **Rationale:** Five milliliters is too large an amount to inject into one site. The nurse needs to divide the amount into two 2.5-mL injections. A 3-mL syringe could be used (option 1). The length of the needle will depend on the muscle development of the client. The nurse needs to assess the client. The presumption, based on the information provided, is that this client's muscle mass is within normal limits. The needle length would need to be 1 1/2 inches because the medication is be given "deep IM" (option 5). This also suggests that the medication should be given in the preferred site for IM injections—the ventrogluteal site—because it provides the greatest thickness of gluteal muscle. The gauge of the needle for an IM injection into the ventrogluteal muscle can range between #20 and #23 (option 3). The nurse needs to assess the viscosity of the medication. Smaller gauges (e.g., #23) produce less tissue trauma; however, viscous solutions may require a larger gauge (e.g., #20–#21). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-5.
4. **Answer:** 3. **Rationale:** The type of syringe for subcutaneous injections depends on the medication to be given. This

situation does not indicate that the medication is insulin and, thus, another syringe is needed. Generally a 2-mL syringe is used for most subcutaneous injections. Generally, a #20- to #23-gauge needle is used for IM injections. Needle size and length are based on the client's body mass, the intended angle of insertion, and the site of the injection. Generally, a #25-gauge, 5/8-inch needle is used for adults of normal weight and the needle is inserted at a 45° angle. Because 2 inches of tissue can be grasped or pinched at the site of the injection, the nurse should administer the medication at a 90° angle to ensure the medication reaches subcutaneous tissue. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-18b.

5. **Answer:** 1. **Rationale:** A tuberculin test is given by intradermal injection. A tuberculin syringe is used because the dosage will most likely be 0.1 mL. A short, fine needle is needed to avoid entering the subcutaneous tissue. The needle should have a short bevel and usually be between #25 and #27 gauge. The needle should be between 1/4 to 5/8 inch long. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-18a.
6. **Answer:** 4. **Rationale:** If the nurse goes by the amount of the medication (0.5 mL) only, the deltoid muscle would be the site. However, knowing and assessing the client is critical. The muscles of an older, emaciated client will most likely be diminished or atrophied. The nurse should consider the ventrogluteal site because that site will have the most muscle mass. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcomes:** 35-17c; 35-12.
7. **Answer:** 1. **Rationale:** Due to renal insufficiency, the dose of the medication would need to be decreased in order to avoid accumulation of the medication and the risk of toxicity. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 35-12.
8. **Answer:** 2. **Rationale:** To straighten the ear canal in children less than 3 years of age, the ear must be pulled down and back. In individuals over 3 years of age, the ear is pulled up and back. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-20c.
9. **Answer:** 0.375 or rounded to 0.38 mL. **Rationale:** After converting to like numbers, the formula would be set up as follows:

   400 micrograms = 1 mL

   150 micrograms = X mL

   Cross multiply $(400X = 150)$

   Divide by 400

   $X = 0.375$

   Cognitive Level: Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-9.
10. **Answer:** 3, 4, 1, 5, 2, 6, 7, and 8. **Rationale:** This is the correct order for this skill—first the nurse mixes the insulin, assesses the skin, and cleanses the skin. The nurse would then pinch the skin, insert the needle, inject the medication, count to five, and remove the syringe. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-18b.

CHAPTER 36 Skin Integrity and Wound Care

1. **Answer:** 2. **Rationale:** A score ranging from 15 to 18 is considered at risk and a turning schedule is appropriate. Option 1 requires a score above 18 (normal and ongoing assessment is indicated). Option 3, moderate risk, for which a transparent barrier would be appropriate, is applied to clients with scores of 13 to 14. Option 4, very high risk, is assigned for those with a score of 9 or less. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Management. **Nursing Process:** Implementation. **Learning Outcome:** 36-2.
2. **Answer:** 1. **Rationale:** Wound culture specimens should be obtained from a cleaned area of the wound. Microbes responsible for the infection are more likely to be found in viable tissue. Collected drainage contains old and mixed organisms. An appropriate specimen can be obtained without causing the client the discomfort of debriding. The nurse does not generally debride the wound to obtain a specimen. Once systemic antibiotics have been begun, the interval following a dose will not significantly affect the concentration of wound organisms. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 36-13b.
3. **Answer:** 3. **Rationale:** Hydrocolloid dressings protect shallow injuries and maintain an appropriate healing environment. Alginates (option 1) are used for wounds with significant drainage; dry gauze (option 2) will stick to new granulation tissue, causing more damage. A dressing is needed to protect the wound and enhance healing. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 36-12.
4. **Answer:** 1. **Rationale:** The heating pad needs to be removed. After 30 minutes of heat application, the blood vessels in the area will begin to exhibit the rebound effect, resulting in vasoconstriction. Lowering the temperature, but still delivering heat—dry or moist—will not prevent the rebound effect. The visual appearance of the site on inspection (option 3) does not indicate if rebound is occurring. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 36-14.
5. **Answer:** 3. **Rationale:** Immobile and dependent clients should be repositioned at least every 2 hours, not every 4, so this client or family member requires further teaching. Warm water and moisturizing damp skin are correct techniques for skin care. Red areas that do not return to normal skin color should be reported. It would also be correct to use a foam pad to help relieve pressure. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 36-10.
6. **Answer:** Potential pressure injury sites for side-lying clients include ankles, knees, trochanters, ilia, shoulders, and ears. These are important areas to assess. Other answers may also be correct. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 36-8.
7. **Answer:** 1, 2, 3, and 5. **Rationale:** Option 4 is not correct. The suture material that is visible is in contact with bacteria and must not be pulled beneath the skin during removal. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process**: Implementation. **Learning Outcome:** 36-13e.
8. **Answer:** 1, 3, and 4. **Rationale:** Risk factors for pressure injuries include low-protein diet, lengthy surgical procedures, and fever. Protein is needed for adequate skin health and healing. During surgery, the client is on a hard surface and may not be well protected from pressure on bony prominences. Fever increases skin moisture, which can lead to skin breakdown, plus the stress on the body from the cause of the fever could impair circulation and skin integrity. Insomnia (option 2) would generally involve restless sleeping, which transfers pressure to different parts of the body and would reduce the chances of skin breakdown. A waterbed (option 5) distributes pressure more evenly than a regular mattress and, thus, actually reduces the chances of skin breakdown. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 36-1.
9. **Answer:** 1, 2, and 4. **Rationale:** To irrigate a wound, the nurse uses clean gloves to remove the old dressing and to hold the

basin collecting the irrigating fluid. A mask should be worn when splashing can occur such as when irrigating a wound. A 60-mL syringe is the correct size to hold the volume of irrigating solution plus deliver safe irrigating pressure. The irrigation fluid should be room or body temperature—certainly not refrigerated. Forceps may be used to remove or apply a dressing but are not required for irrigation. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 36-13c.

10. **Answer:** 2. **Rationale:** Gauze bandages are used to hold absorbent dressings in place. How tight the bandage is applied depends on the purpose (option 1). Elastic bandages are generally not sterile because they are used to support a body part and not cover a wound (option 3). The bandage may or may not cover at least one joint of the limb (option 4).

    Cognitive Level: Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 36-13d.

CHAPTER 37 Perioperative Nursing

1. **Answer:** 3. **Rationale:** These tests are specific to liver function. Option 1 evaluates fluid and electrolyte status. Option 2 evaluates renal status; option 4 evaluates nutritional status. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 37-3.
2. **Answer:** 2. **Rationale:** Grieving is the state in which an individual experiences reactions in response to an expected significant loss and is often characterized by negative responses such as shame, embarrassment, guilt, or revulsion. Option 3, fear, is usually characterized by feelings of dread, fright, apprehension, or alarm. Impaired coping, option 4, is usually characterized by verbalization of inability to cope or ask for help, inappropriate use of defense mechanisms, or inability to meet role expectations. **Cognitive Level:** Applying. **Client Need:** Psychologic Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 37-4.
3. **Answer:** 4. **Rationale:** Option 1 is incorrect because of the ASA guidelines for preoperative fasting. Option 2 is incorrect because clients are taught how to cough and also how to splint their incision to prevent complications. Option 3 is incorrect because anticoagulants are discontinued a few days before surgery to avoid excessive bleeding postoperatively. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 37-6.
4. **Answer:** 2. **Rationale:** The symptoms describe decreased cardiac output and not any of the other listed complications. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 37-10.
5. **Answer:** 3. **Rationale:** Options 1 and 2 are incorrect because the client is still recovering from the anesthesia used during surgery. Option 4 is incorrect because pain usually decreases after the second or third postoperative day. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 37-10.
6. **Answer:** Splinting. **Rationale:** If the incision is painful when the client coughs, splinting the abdomen may reduce the pain. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 37-6.
7. **Answer:** 2, 3, and 5. **Rationale:** Options 2, 3, and 5 are all part of safety protocols to avoid wrong site, wrong procedure, and wrong person surgery. The Joint Commission does not specify the type of mark, but whatever mark is used, it must be used consistently throughout the facility. Option 1 is giving false reassurance and does not address the client's fear. Placing an X on the wrong knee is confusing and could result in wrong-site surgery (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 37-7.
8. **Answer:** 1 and 3. **Rationale:** The absence of nausea and vomiting indicates that the client may be ready for clear liquids. Anesthetics, narcotics, fasting, and inactivity all inhibit peristalsis. Oral fluids and food are started after the return of peristalsis. The client may feel hungry but peristalsis may not be present (option 5). Options 2 and 4 are important but not related specifically to advancing the client's diet. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 37-9.
9. **Answer:** Safety. **Rationale:** The client's protective reflexes are compromised, especially with general anesthesia. Thus, the perioperative nurse needs to maintain the client's safety during surgery. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 37-5.
10. **Answer:** 3, 4, and 5. **Rationale:** Preoperative teaching (option 1) includes assessment of the client's learning needs and determining the teaching content and strategies that require professional knowledge and cannot be assigned. However, the AP can reinforce what the nurse has taught the client (option 3). Managing GI suction (option 2) requires application of knowledge and problem-solving and is not assigned to AP. The AP, however, can assist with emptying the drainage receptacle and reporting changes in amount and color of the drainage to the nurse (option 5). AP frequently remove and reapply antiemboli stockings (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process**: Implementation **Learning Outcome:** 37-14.

CHAPTER 38 Sensory Perception

1. **Answer:** 4. **Rationale:** A sudden, unexpected admission for surgery may involve many experiences (e.g., lab work, x-rays, signing of forms) while the client is in pain or some form of discomfort. The time for orientation will thus be lessened. After surgery, the client may be in pain and possibly in a critical care setting. Options 1 and 2 reflect a greater risk for sensory deprivation, and option 3 is a normal activity for a teenager. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 38-3.
2. **Answer:** 3. **Rationale:** The transfer to a different setting can change the amount or patterning of incoming stimuli accompanied by a diminished, exaggerated, distorted, or impaired response to such stimuli. The onset of restlessness and agitation is a characteristic of disturbances in thinking. Options 1 and 2: There is no evidence of longstanding or progressive deterioration of intellect and personality. Option 4: diminished personal relationships is related to a disturbance in self-concept. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 38-6.
3. **Answer:** 2. **Rationale:** Because of the paraplegia (paralysis of lower body), the client is unable to feel discomfort. The client will be taught to lift self using chair arms every 10 minutes if possible. Option 1 is an actual problem versus a potential problem. In option 3, the client wears glasses that help correct the poor vision. Option 4 is more of a potential for injury diagnosis. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 38-6.
4. **Answer:** 2. **Rationale:** This client could use an assistive device that flashes a light when the doorbell rings. Option 1 relates to safety of the environment rather than sensory alteration. Options 3 and 4 reflect how the client adapts to the sensory alteration. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 38-7.
5. **Answer:** 4. **Rationale:** Option 4 is the only response that helps orient the client and treats the client with respect. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 38-7.

6. **Answer:** 1, 3, and 4. **Rationale:** Options 2 and 5 relate to interventions for a client with a hearing impairment. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 38-7.
7. **Answer:** 3. **Rationale:** A disorganized, cluttered environment increases confusion. Option 1: Keeping the room well lit during waking hours promotes adequate sleep at night. It is important to eliminate unnecessary noise (option 2). The client does not meet the standard criteria for restraint application (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 38-8.
8. **Answer:** 2, 4, and 5. **Rationale:** Options 1 and 3 are clinical signs of sensory overload. **Cognitive Level:** Remembering. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 38-3.
9. **Answer:** Identifying taste: 5; Stereognosis: 3; Snellen chart: 1; Identifying aromas: 4; Tuning fork: 2. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 38-4.
10. **Answer:** 1. **Rationale:** The amplified telephone helps with hearing and provides a means for communicating with others. Option 2 refers to a tactile impairment. Option 3 relates to a visual impairment, and option 4 an olfactory impairment. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 38-7.

CHAPTER 39 Self-Concept

1. **Answer:** 1. **Rationale:** Sally has an inappropriate view of her physical self, which is body image. Personal identity is a sense of uniqueness (option 2); self-expectation consists of those things one believes the self should be able to do (option 3); and core self-concept includes the most vital central beliefs about one's identity (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 39-2.
2. **Answer:** 3. **Rationale:** This is role conflict—several different roles are competing for the individual's time, energy, and abilities. Role ambiguity results when there are unclear expectations of the role (option 1). Role strain exists when there are feelings of inadequacy in performing a role (option 2). Role enhancement is a nursing intervention (option 4). **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 39-2.
3. **Answer:** 2. **Rationale:** This is a realistic and measurable outcome. Restored self-esteem is vague and not measurable (option 1). Teaching is an intervention, not an outcome (option 3). Decreased preoccupation with altered self relates to body image rather than self-esteem (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 39-6.
4. **Answer:** 1. **Rationale:** This response encourages the client to say more and focuses on the positive. Option 2 is condescending and closes the discussion. Both options 3 and 4 ignore the emotional component of the client's statement and do not address the client's feelings of worthlessness. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcomes:** 39-6; 39-7.
5. **Answer:** 4. **Rationale:** An individual who follows the crowd is demonstrating unsuccessful resolution of this task. Successful resolution would result in assertion of independence (option 1). Inability to express desires is symptomatic of unresolved toddlerhood autonomy versus shame and doubt (option 2), while difficulty being a team player suggests unresolved early school-age industry versus inferiority (option 3). **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 39-1.
6. **Answer:** 3. **Rationale:** Self-awareness consists of the relationship between own and others' perceptions of the individual. The other options reflect only how the nurse sees himself or herself. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 39-2.
7. **Answer:** 1. **Rationale:** An individual who perceives herself primarily in terms of relationships with others must have the ability to perform those roles considered in planning care. Although it may seem important for her to develop outside interests, she may not be able to do this, especially with a new diagnosis of a chronic condition. It is not mandatory for the family to be present during care planning, although items impacting their lives should be validated with them before the plan is finalized. Psychologic counseling is not automatically indicated unless her role performance is unhealthy. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcomes:** 39-4; 39-6.
8. **Answer:** 2 and 5. **Rationale:** An individual with chronic low self-esteem often is able to only make negative statements about self. The client would have difficulty confronting authority (option 1). Option 3 relates to role performance. Option 4 is incorrect because the client would have difficulty achieving even common or realistic goals and is not likely to set extremely high goals. Option 6, sleeping, is generally not impaired with low self-esteem. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 39-5.
9. **Answer:** 2 and 3. **Rationale:** The client with poor self-concept should be encouraged to say positive self-statements and minimize negative ones. Such clients should not be encouraged to compare themselves with others (option 1). Having them care for others can be a very therapeutic intervention for such individuals (option 4). They should be given realistic and normal levels of expectations for their behavior. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 39-6.
10. **Answer:** 4. **Rationale:** The social self is how one is perceived by others and is difficult, if not impossible, to influence since the client does not control the viewpoints of others. With planning, the number of the client's resources can be increased, self-knowledge improved, and core self-concept broadened since these are within the client's control. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 39-3.

CHAPTER 40 Sexuality

1. **Answer:** 4. **Rationale:** Clients still may feel shame and discomfort regarding sexuality. Most clients assume that providers have a great deal of information (option 1). Many clients have questions and concerns (option 2). Although talking with someone of the same gender may make it easier for some women, it is not a requirement for assessment and intervention (option 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 40-1.
2. **Answer:** 2. **Rationale:** Transgender individuals' anatomic gender is not the same gender as they feel themselves to be. Option 1 is the definition of intersex. Option 3 is the definition of bisexuality. Gender identity is a lifelong belief and not altered by an acute condition (option 4). **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 40-3.
3. **Answer:** 4. **Rationale:** Masturbation is a normal activity for most individuals and assists with self-exploration of sexuality. There is no evidence that masturbation interferes with academic achievement (option 2). Individuals masturbate at all ages of life (option 3). **Cognitive Level:** Understanding.

Client Need: Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 40-5.

4. **Answer:** 2. **Rationale:** Orgasmic response and sex drive are often inhibited by antidepressants. If the depression lifts, there may be an improvement but the focus in option 1 is on the partner rather than where it should be—on the client. Retrograde ejaculation is associated with removal of the prostate gland (option 3). Skin hypersensitivity is not a side effect of antidepressant medications (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 40-8.
5. **Answer:** 4. **Rationale:** More information is needed before intervening. Also, the client needs the opportunity to express her feelings. Option 1 is an unprofessional response and false reassurance. The ANA *Code of Ethics* indicates that clients are entitled to a timely and appropriate response to their needs. Option 2 suggests postponing the discussion and that the primary care provider is the better healthcare provider to deal with her concerns, which is untrue. Option 3 represents feeding into her negative self-concept and inappropriate self-disclosure. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 40-4.
6. **Answer:** 1. **Rationale:** Dyspareunia is painful intercourse. Knowledge of the partner's awareness will contribute to resolution. Involuntary vaginal spasms are called vaginismus (option 2). Painful menstruation is called dysmenorrhea (option 3). Breast swelling can occur during portions of the menstrual cycle but is unrelated to painful intercourse (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcomes:** 40-6; 40-7.
7. **Answer:** 3. **Rationale:** Antihypertensive medications are known to affect sexual functioning in several different ways, so some focused history questions would be indicated. There is no evidence of a relationship between sexual functioning and anti-inflammatories, hypnotics, or antihistamines (options 1, 2, and 4). However, the underlying condition that leads the client to take other medications could be important. Side effects of any medication could impact sexual interest or energy level, which reinforces the importance of including taking a sexual health history for all clients. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcomes**: 40-6; 40-7; 40-8.
8. **Answer:** 2. **Rationale:** LI includes instructing clients regarding when sexual activity is safe or unsafe. P involves giving permission to be sexual beings and to discuss issues (option 1). SS includes specific suggestions that help clients promote optimal functioning (option 3). Intensive therapy (IT) requires special skills offered by a nurse specialist or sex therapist (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcomes:** 40-1; 40-9.
9. **Answer:** 4. **Rationale:** A change in sexual frequency is not abnormal but may suggest an opportunity to improve his knowledge. It does not suggest pathology or altered body image (options 1 and 2). It would be incorrect to assume his lifestyle is inactive merely because the frequency of his sexual activity has decreased (option 3). Further assessment of the reason for the decrease in sexual activity is indicated. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Diagnosing. **Learning Outcomes:** 40-1; 40-2; 40-4; 40-8.
10. **Answer:** 3. **Rationale:** The key term is *ineffective*. If the suggestions given by the nurse are ineffective in reaching the desired goals, the client may require intervention from someone with more specialized skills. Verbalizing constructive methods of modifying sexual activity are healthy responses and do not require a more skilled therapist (option 1). The generalist nurse can refer the client to education and support groups (option 2). Experimenting with new sexual activities is probably a healthy direction and does not suggest the need for referral (option 4). **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 40-8.

CHAPTER 41 Spirituality

1. **Answer:** 4. **Rationale:** Options 1 and 2 involve assessment and diagnosis, not planning. Option 3, simply keeping the client busy, does not necessarily contribute to feeling fulfilled or purposeful. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcomes:** 41-1; 41-3; 41-5.
2. **Answer:** 3. **Rationale:** The best initial response is to assess. Option 1 may be interpreted as distancing by the client. Option 2 inserts the nurse's experience, which is generally inappropriate. Option 4 is not appropriate for someone in spiritual distress. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcomes:** 41-4; 41-5.
3. **Answer:** 3. **Rationale:** The key term is *full*. Option 1 would be inadequate, option 2 is only partial presencing, and option 4 is transcendent presencing. **Cognitive Level:** Remembering. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 41-5.
4. **Answer:** 3. **Rationale:** This client portrays no disruption (option 1) or potential for disruption (option 2), but rather the potential for enhanced spiritual health as a result of the transformative illness experience. Option 4 is not a valid diagnosis. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosis. **Learning Outcomes:** 41-1; 41-2.
5. **Answer:** 4. **Rationale:** Assessment is always the first step of the process of spiritual caregiving or any nursing activity. Options 1, 2, and 3 may not respect the spiritual beliefs of either the nurse or the client. While an assessment may lead the nurse to share personal beliefs, these are never urged on the client. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcomes:** 41-1; 41-6; 41-7.
6. **Answer:** 3. **Rationale:** Many older adults are religious and spiritually aware. Options 1, 2, and 4 are disputed by recent research evidence. **Cognitive Level:** Remembering. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcomes:** 41-1; 41-3.
7. **Answer:** 3. **Rationale:** Options 1, 2, and 4 are potentially uncaring or unethical. Jehovah's Witnesses have a well-developed network of representatives who can be called to explain and explore medical options with their fellow believers and medical staff. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcomes:** 41-1; 41-5; 41-7.
8. **Answer:** 2. **Rationale:** Residing in the skilled nursing facility likely will curb the client's participation in her church. Options 1, 3, and 4 are incorrect because it is not known if the relocation or an alteration in religious practice will affect her spiritual health in either a negative or positive way. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosis. **Learning Outcomes:** 41-1; 41-2; 41-4.
9. **Answer:** 4. **Rationale:** Recognizing personal emotional responses to events that parallel those experienced by a client allows a nurse to identify an empathic response to a client's spiritual or emotional need. Options 1, 2, and 3 fail to show a nurse drawing deep to recognize inner experience that can inform empathy. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 41-8.

10. **Answer:** 1. **Rationale:** Although the mother is arguably angry, it is unknown whether this anger is impairing her religiosity or her coping. More data are needed before determining that either option 2 or 3 is the best diagnosis. The mother is experiencing distress versus being at risk for it (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosis. **Learning Outcomes:** 41-2; 41-4.

CHAPTER 42 Stress and Coping

1. **Answer:** 3. **Rationale:** Taking on additional work would only serve as an additional stressor. In addition, a nurse who has not begun resolution of feelings is unlikely to be able to meet clients' emotional needs. Effective coping may include verbalizing feelings (one-on-one or in groups) or initiating distractions (options 1, 2, and 4). Of course, the nurse may not disclose confidential information to her partner or others who would not already have this information. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 42-6.
2. **Answer:** 4. **Rationale:** Wearing glasses is another example of beginning a new strategy to assist with what will be a lifelong health need even though it is not necessarily a desired change. Interviewing for a job (option 1) is a very short-lived situational stressor. Coping strategies effective while a teenager may not be relevant at age 50 (option 2). Experiencing the stress of a divorce is a social and role stressor quite unlike that of a health problem (option 3). **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 42-9.
3. **Answer:** 1. **Rationale:** In the transaction model, stress is a very personal experience and varies widely among individuals. Option 2 represents the stimulus model, and option 3 represents the response model of stress. In option 4, external resources and support are a factor in determining stress levels but omit the key aspects of internal personal influences. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 42-1.
4. **Answer:** 3. **Rationale:** With stress, respirations increase, pupils dilate, peripheral blood vessels constrict, and the heart rate increases. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 42-3.
5. **Answer:** 2. **Rationale:** It is too soon for caregiver stress to be an appropriate nursing diagnosis—especially since the child is not at home. Denial and fear are common reactions to this type of threat (options 1 and 3). The father demonstrates impaired family coping by his difficulty in being supportive (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 42-8.
6. **Answer:** 1, 3, and 4. **Rationale:** Common stressors among young adults include marriage, starting a new job, and leaving the parental home. Stressors from aging parents are more common among middle-aged adults (option 2); decreased physical abilities is a stressor in older adults (option 5); and changing body structure serves as a stressor in both children and older adults (option 6). **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 42-7.
7. **Answer:** 2. **Rationale:** All four areas of health promotion strategies may be important, but for this client sleep is likely to be the most adversely affected by travel in which changing time zones and unfamiliar sleeping quarters are common. It is easier for clients to adapt to modifying exercise (option 1), nutrition (option 3), and time management (option 4) during travel than it is to control sleep. Thus, it becomes the most important area requiring intervention to avoid worsening the existing stress. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 42-9.
8. **Answer:** 4. **Rationale:** Unless the nurse feels in physical danger, it is important to remain with the client, allow the anger to dissipate, and then begin assessing the cause. Leaving the room provides no therapeutic action (option 1). Option 2 may be considered setting limits, which can be helpful, but cannot occur until the client is calmer. All behavior is meaningful; it is inappropriate to ignore the client's behavior (option 3). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 42-9.
9. **Answer:** 1. **Rationale:** This client is exhibiting severe anxiety and, therefore, learning is impaired but not impossible (see Table 42.2). Therefore, it is most appropriate for the nurse to teach only those things that are critical for the client to learn at this time. The nurse also recognizes that learning may not be retained at this level of anxiety and plans to reinforce the teaching when the client is less anxious. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 42-4.
10. **Answer:** 1, 2, and 4. **Rationale:** Compensation (option 1) may allow the client to overcome a weakness. Displacement (option 2) allows the client to express feelings safely. Repression (option 4) protects the client from further emotional trauma until able to cope. Minimization (option 3) prevents the client from accepting responsibility for actions. Regression (option 5) returns the client to a lower or previous developmental level. *Note:* Each of these may be more or less effective defenses depending on the exact context of the situation. **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 42-5.

CHAPTER 43 Loss, Grieving, and Death

1. **Answer:** 1, 2, and 3. **Rationale:** Correct answers include abbreviated (normal grief that is briefly experienced), anticipatory grief (experienced before the loss or death but appropriate), and disenfranchised grief (the emotions are felt privately, just not expressed in public). Unhealthy abnormal types of grief include complicated grief (option 4) in several different forms: Unresolved grief is extended in length and severity (option 5). With inhibited grief, symptoms are suppressed, and other effects, including somatic, are experienced instead (option 6). **Cognitive Level:** Remembering. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 43-2.
2. **Answer:** 2. **Rationale:** When possible, modifications of policy that demonstrate respect for individual differences should be explored. The primary care provider is in no position to modify the implementation of hospital policy (option 3). Utilizing an empty room and a staff member for a deceased client is an inappropriate use of resources (option 4). **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 43-8.
3. **Answer:** 1. **Rationale:** This statement acknowledges the family's grief simply. Avoid statements that may be interpreted as overly impersonal (option 2), false support (option 3), or harsh (option 4). **Cognitive Level:** Application. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 43-8.
4. **Answer:** 3. **Rationale:** Until children are about 5 years old, they believe that death is reversible. Between ages 5 and 9, the child knows death is irreversible but believes it can be avoided (option 2). Between 9 and 12 years of age, the child recognizes that he or she, too, will someday die (option 3). At 12 to 18 years old, the child builds on previous beliefs and may fear death, but often pretends not to care about it (option 4). **Cognitive Level:** Remembering. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 43-4.
5. **Answer:** 4. **Rationale:** Adaptive responses indicate the client can put the loss into perspective and begin to develop

strategies for coping with the loss. Although the other options are responses the client might likely give and feel, and are not pathologic, they do not demonstrate movement toward a goal of adaptation or problem-solving. **Cognitive Level:** Application. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 43-3.

6. **Answer:** 1. **Rationale:** The nurse needs to assess and explore the meaning of the client's crying. Options 2 and 4 leap to assumptions about the meaning of the tears and ignore the possibility of the client's distress. Option 3 suggests that the client has the same feelings as the nurse, which may not be correct. **Cognitive Level:** Application. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 43-3.
7. **Answer:** 4. **Rationale:** Quality of life is determined by the client and expressed in terms of his or her satisfaction with a variety of aspects of life. Although being able to pay for care (option 1), having apparent spiritual peace (option 2), and absence of physiologic complications (option 3) may appear to contribute to good quality of life, only the client's expression of satisfaction can provide the data the nurse requires to evaluate the goal. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 43-5.
8. **Answer:** 4. **Rationale:** To plan with and assist the family, the nurse needs more data regarding the family's reactions to their loss. Information on issues such as insurance coverage (option 1) can wait until later and may be more appropriately the responsibility of social services rather than the nurse. It is important for the nurse to determine their understanding of their injuries but they are stated as not life-threatening (option 2). Once the nurse has assessed the family's responses it will be important to determine availability of outside resources to assist them (option 3). **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 43-1.
9. **Answer:** 3. **Rationale:** If there is no heartbeat, the client has died. Before death, the blood pressure may not be able to be heard on auscultation because it is very low (option 1). Loss of the gag reflex (option 2) occurs with loss of muscle tone but can exist in many circumstances unrelated to dying. Vasodilation and pooling of fluids at the end of life may cause cool and darkened extremities but these are not reliable signs of death (option 4). **Cognitive Level:** Comprehension. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 43-6.
10. **Answer:** 1. **Rationale:** Assisting the client to die with dignity involves allowing the client to participate in and choose the direction of the remainder of his or her life. Sharing the nurse's own views about life after death (option 2) does not enhance client dignity. The nurse should not assume that avoiding talking about dying and emphasizing the present (option 3) is therapeutic for the client. Only if the client wishes to have someone else perform care is doing so supporting death with dignity (option 4). Otherwise, it may have the opposite effect. **Cognitive Level:** Application. **Client Need:** Psychological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 43-7.

CHAPTER 44 Activity and Exercise

1. **Answer:** 2. **Rationale:** A key word in the question is *base*, and the feet provide this foundation. Leaning backward actually decreases balance (option 1), and tensing abdominal muscles alone (option 3) or bending the knees (option 4) does not affect the base of support. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 44-7.
2. **Answer:** 1, 3, and 5. **Rationale:** Isotonic exercise increases muscle tone, mass, and strength; maintains joint flexibility; and improves circulation. During isotonic exercise, both heart rate and cardiac output quicken to increase blood flow to all parts of the body (option 4). Little or no change in blood pressure occurs (option 2). **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 44-2.
3. **Answer:** 1. **Rationale:** Vital signs that do not return to baseline 5 minutes after exercising indicate intolerance of exercise at that time. This is a real problem, not "potential for," as in option 2. There is no evidence that the client has self-esteem problems (option 3), or is in danger of falling (option 4). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 44-6.
4. **Answer:** 3. **Rationale:** Although the crutches (or cane) are always used along with the weaker leg, the weaker leg should go down the stairs first. The stronger leg can support the body as the weaker leg moves forward. All of the other statements are correct. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 44-9.
5. **Answer:** 4. **Rationale:** When the client performs the movements systematically, using the same sequence during each session, the nurse can evaluate that the teaching was understood and is successful. When performing active ROM the client should exercise to the point of slight resistance, but never past that point of resistance in order to prevent further injury (option 1). The client should perform each exercise at least three times, not just once (option 2). The client should perform each series of exercises twice daily, not just once per day (option 3). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 44-8.
6. **Answer:** 1. **Rationale:** Normal gait involves a level gaze, an initial rotation beginning in the spine, heel strike with follow-through to the toes, and opposite arm and leg swinging forward. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 44-5.
7. **Answer:** 1, 4, and 5. **Rationale:** Eating and bathing will flex the elbow joint, and grasping and manipulating utensils to eat and write will take the thumb through its normal ROM. Walking flexes the hip. Shaving and eating require elbow flexion, not extension (option 2). Writing brings the fingers toward the inner aspect of the forearm, thus flexing the wrist joint (option 3). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 44-1.
8. **Answer:** 3. **Rationale:** It is prudent for nurses to understand and use proper body mechanics at all times to decrease risk, while keeping in mind the importance of assistive devices and help from other staff. While it is generally accepted that proper body mechanics alone will not prevent injury, many work settings do not yet have "no manual lift" and "no solo lift" policies and resources in place. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 44-7.
9. **Answer:** 4. **Rationale:** Placing the client in a safe position is the best maneuver. Leaving the client creates unsafe conditions because the client may faint before being able to return to her room (options 1 and 2). Rapid, shallow breathing (hyperventilation) may increase the dizziness (option 3). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 44-10g.
10. **Answer:** 2. **Rationale:** The reddened area of the skin can lead to skin breakdown. The other options are within normal limits. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 44-3g.

CHAPTER 45 Sleep

1. **Answer:** 2. **Rationale:** This is the brainstem where the reticular formation (and RAS) is located and which integrates sensory information from the peripheral nervous system and relays the information to the cerebral cortex. An intact cerebral cortex and reticular formation are necessary for the regulation of sleep and waking states. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 45-1.
2. **Answer:** 4. **Rationale:** Most clients with sleep apnea report excessive daytime sleepiness. If they don't volunteer this, clients should be asked if they fall asleep or struggle to stay awake at work. Although cardiac arrhythmias may occur, they are usually only detectable during a sleep study, and thus the client would not be aware of them (option 1). Nasal obstruction is rarely the cause of sleep apnea or a complaint of clients with sleep apnea (option 2). There are many causes of chest pain, and this is unlikely to be something reported by clients with sleep apnea unless they have underlying cardiac disease (option 3). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 45-6.
3. **Answer:** 2. **Rationale:** Falling asleep within 20 to 30 minutes is normal for adults and would represent substantial improvement in the client's difficulties. Most adults do not need to sleep 8 to 10 hours per day (option 1). Although it would be ideal to remove the source of the client's stress, he is unlikely to have a plan to pay all his bills within 5 days (option 3). Distraction or keeping busy until bedtime will not prevent the client from worrying about his bills at bedtime (option 4). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 45-7.
4. **Answer:** 4. **Rationale:** Suddenly stopping barbiturate sleeping pills can precipitate a dangerous withdrawal. Doses should be tapered gradually and the tapering process supervised by the client's primary care provider. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 45-4.
5. **Answer:** 1. **Rationale:** Preschool children require 10 to 12 hours of sleep per night. Young children often rise early, so it is more appropriate to put the child to bed earlier in the evening. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 45-3.
6. **Answer:** 1, 3, and 5. **Rationale:** It is important to find out if he is obtaining sufficient sleep. If he gets more sleep on weekends than weekdays, insufficient sleep may be the cause of his difficulties staying awake in class. It is important to determine if his symptoms are chronic (e.g., longer than 3 months) or if they are of recent onset. Some prescribed and over-the-counter medications and herbal remedies can cause sleep disturbances. Although alcohol abuse or binge drinking can cause health problems, neither is likely to cause excessive daytime sleepiness (option 2). Unless the client is sleep deprived, boring classes will not induce sleep (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 45-6.
7. **Answer:** 4. **Rationale:** The client's symptoms, combined with his weight, suggest that he has obstructive sleep apnea and should be referred to a sleep disorders specialist for further evaluation. It would not be wrong to refer him to a dietitian for weight-loss counseling (option 2), but being evaluated by a sleep disorders specialist is more critical. Drinking alcohol or taking sleeping pills is not advised in clients with sleep apnea because they disrupt the client's sleep patterns (option 3). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 45-5.
8. **Answer:** 1. **Rationale:** Reducing exposure to bright light in the morning, when driving home, and when going to sleep will make it easier to fall asleep after work. Exercising before going to bed will increase arousal (option 2). Caffeine consumed at the beginning of a 12-hour shift will not assist the nurse in remaining awake during the latter part of the shift (option 3). Although working in a brightly lit area will reduce drowsiness, this strategy is rarely available to nurses working the night shift; lights are often dimmed in hospital corridors and client rooms (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 45-7.
9. **Answer:** 3. **Rationale:** Napping frequently reappears in older adults. Unless the client has difficulty falling asleep at night, there is no reason he should not be allowed to take a 15- to 20-minute nap in the early afternoon. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 45-3.
10. **Answer:** 1, 3, and 4. **Rationale:** Reducing environmental noise, as well as the number of times she is disturbed for medications and vital signs, will reduce the likelihood that she will awaken during the night. Delivering necessary care at 1.5- or 3-hour intervals is consistent with multiples of the 90-minute sleep cycle. Since it is unlikely that all of the noise in the environment can be eliminated, using a fan to generate a steady background noise may help mask sounds of individuals talking, carts being moved through the halls, and other noise. Music is not usually recommended because it can be interesting to listen to, thus encouraging wakefulness (option 2). The room temperature needs to be satisfactory for the client. A room that is too warm is not usually conducive for sleep (option 5). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 45-8.

CHAPTER 46 Nutrition

1. **Answer:** 2. **Rationale:** A BMI of 30 to 40 indicates moderate to severe obesity. A BMI of less than 18.5 indicates underweight, which may be due to inadequate dietary intake (option 1) or undernutrition (option 4). The nursing diagnosis of overweight is defined by a BMI of 25–29.9 (option 3). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Diagnosing. **Learning Outcome:** 46-13.
2. **Answer:** 4. **Rationale:** This client needs more grains in the diet. The client should have 6 to 7 oz grains per day, 3 cups/week dark green vegetables, 2 cups/week orange vegetables, 3 cups/week legumes, 3 cups/week starchy vegetables, 1.5 to 2 cups fruit per day, 5 to 6 oz meat and beans per day, and 3 cups milk, yogurt, and cheese per day. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 46-5.
3. **Answer:** 2, 3, 4, 6, and 8. **Rationale:** A full liquid diet contains only liquids or foods that turn to liquid at body temperature. Pudding, juices, hard candy, Cream of Wheat cereal, and fruit smoothies are permitted on a full liquid diet. Scrambled eggs (option 1), mashed potatoes (option 5), and oatmeal cereal (option 7) are not permitted until the client advances to a soft diet. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 46-9.
4. **Answer:** 3. **Rationale:** Gastric secretions are acidic as evidenced by a pH of less than 6. If the tube were improperly placed in the client's airway, speaking would usually be impaired (option 1). Gagging during insertion is common and does not indicate that the tube is in the stomach (option 2). Ability to easily instill fluid into the tube does not relate to its placement. The lungs would offer no resistance to the flow

of liquid (option 4). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 46-10a.

5. **Answer:** 1. **Rationale:** For proper flow, the feeding container hangs 1 foot above the tube insertion. Feedings may be administered if there is less than 90 to 100 mL of residual volume (unless agency policy specifies otherwise) (option 2). To prevent or reduce the risk of aspiration, the client should be placed in Fowler's position during feeding (option 3). The feeding should be warmed to room temperature before administration to decrease cramping and diarrhea (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 46-10c.
6. **Answer:** 1. **Rationale:** The Dietary Guidelines recommend 30 minutes of physical activity on most days of the week to achieve optimal weight. Some individuals benefit from a low-carbohydrate diet, but no particular diet is the solution for all individuals (option 2). A reasonable diet emphasizes balance and portion control rather than forbidding or requiring any specific foods (option 3). Fresh and chemical-free foods may be healthier than preserved foods but do not automatically assist with weight loss (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 46-8.
7. **Answer:** 3. **Rationale:** Always inquire into the client's favorite foods when planning a diet. Dairy may not be indicated for this client due to the high incidence of lactose intolerance in individuals of Asian heritage (option 1). Beer can be a source of calories and, in moderation, is not harmful, and may maintain the client's satisfaction with the dietary changes. The nurse will need to assess the ability to swallow beer safely, however (option 2). Calories from lipid sources should be kept below 35% and, when enhanced wound healing is indicated (not so with a stroke), increased protein and carbohydrates are needed rather than fats (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 46-9.
8. **Answer:** This client has lost 13 pounds, which is 6.7%: (195 – 182)/195 over the 2 months. If the weight loss was steady during the past 2 months, that would indicate a 3.3% loss per month. Less than 5% loss in 1 month is not significant (option 1). However, if this loss continues, the client will exceed 7.5 % over 3 months (option 2) and reach a 10% loss in 3 months, which is a severe loss (option 3). A more detailed assessment is indicated to determine the client's nutritional status. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 46-6; 46-7; 46-8.
9. **Answer:** 2. **Rationale:** A small-bore nasal feeding tube tip is most commonly placed in the stomach. Option 1 indicates the esophagus. A tube tip placed there can lead to aspiration. Option 3 indicates the postpyloric duodenum. Small-bore nasal tubes can be advanced to this location if desired but such a placement is less common than gastric placement. Option 4 indicates the jejunum, where feeding tubes can be placed but usually not from a nasally placed tube. **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 46-10a.
10. **Answer:** 4. **Rationale:** 3 ounces tuna + 2 slices whole wheat bread = 3.1 mg Fe; 1 ounce cheese = ~200 mg Ca^{2+}; pear = 4.2 g fiber. Option 1: 1/3 cup raisins = 1.75 mg Fe; 3 ounces 3 ounces cottage cheese = 90 mg Ca^{2+}; 1 banana = 2.1 g fiber. Option 3: 1/2 cup spaghetti + 2 ounces ground beef = 2.3 mg Fe; 1/2 cup ice cream = 97 mg Ca^{2+}; 1/2 cup lima beans = 3.2 g fiber. Option 2: 3 ounces chicken + 1/2 cup peanuts = 2.9 mg Fe; 1/2 cup broccoli = ~158 mg Ca^{2+}; 1/2 cup broccoli = 2.4 g fiber. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 46-1.

CHAPTER 47 Urinary Elimination

1. **Answer:** 4. **Rationale:** The capacity of the bladder may decrease with age but the muscle is weaker and can cause urine to be retained (option 4). Older adults do not ignore the urge to void and may have difficulty in getting to the toilet in time (option 2). The kidney becomes less able to concentrate urine with age (option 3). **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 47-2.
2. **Answer:** 1, 2, 4, and 5. **Rationale:** The perineum may become irritated by the frequent contact with urine (option 1). Normal fluid intake is at least 1500 mL/day and clients often decrease their intake to try to minimize urine leakage (option 2). UTIs can contribute to incontinence (option 4). A fecal impaction can compress the urethra, which can result in small amounts of urine leakage (option 5). Antihistamines can cause urinary retention rather than incontinence (option 3). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 47-4.
3. **Answer:** 2. **Rationale:** The penis and condom should be checked one-half hour after application to ensure that it is not too tight. A 1-in. space should be left between the penis and the end of the condom (option 1). The condom is changed every 24 hours (option 3), and the tubing is taped to the leg or attached to a leg bag (option 4). An indwelling catheter is secured to the lower abdomen or upper thigh. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 47-10a.
4. **Answer:** 1. **Rationale:** The catheter in the vagina is contaminated and cannot be reused. If left in place, it may help avoid mistaking the vaginal opening for the urinary meatus. A single failure to catheterize the meatus does not indicate that another nurse is needed although sometimes a second nurse can assist in visualizing the meatus (option 2). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 47-10b.
5. **Answer:** 2. **Rationale:** Option 2 is the correct sequence. Option 1 is incorrect because the nurse needs to perform hand hygiene after providing pericare. Option 3 is incorrect because the outside of the kit is not sterile and the nurse would not open the kit with sterile gloves. The current best practice is to not pre-inflate the balloon (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 47-10b.
6. **Answer:** 4. **Rationale:** The key phrase is "the urge to void." Option 1 occurs when the client coughs, sneezes, or jars the body, resulting in accidental loss of urine. Option 2 occurs with involuntary loss of urine at somewhat predictable intervals when a specific bladder volume is reached. Option 3 is involuntary loss of urine related to impaired function. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 47-6.
7. **Answer:** 2 and 4. **Rationale:** Option 2 validates the diagnosis. Cotton underwear promotes appropriate exposure to air, resulting in decreased bacterial growth (option 4). Increased fluids decrease concentration and irritation (option 1). The client should wipe the perineal area from front to back to prevent spread of bacteria from the rectal area to the urethra (option 3). Showers reduce exposure of the area to bacteria (option 5). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 47-7.
8. **Answer:** 2. **Rationale:** The ileal conduit and vesicostomy (options 1 and 4) are incontinent urinary diversions, and clients are required to use an external ostomy appliance to contain the urine. Clients with a neobladder can control their voiding (option 3). **Cognitive Level:** Analyzing. **Client Need:** Health

Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 47-9.

9. **Answer:** 3. **Rationale:** Because the bladder muscles will not contract to increase the intrabladder pressure to promote urination, the process is initiated manually. Options 1, 2, and 4: To promote continence, bladder contractions are required for habit training, bladder training, and increasing the tone of the pelvic floor muscles. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 47-9.
10. **Answer:** 2 and 5. **Rationale:** It is important for the client to inhibit the urge-to-void sensation when a premature urge is experienced. Some clients may need diapers; this is not the best indicator of a successful program (option 3). Citrus juices may irritate the bladder (option 4). Carbonated beverages increase diuresis and the risk of incontinence (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 47-6.

CHAPTER 48 Fecal Elimination

1. **Answer:** 1. **Rationale:** Habitually ignoring the urge to defecate can lead to constipation through loss of the natural urge and the accumulation of feces. Diarrhea will not result—if anything, there is increased opportunity for water reabsorption because the stool remains in the colon, leading to firmer stool (option 2). Ignoring the urge shows a strong voluntary sphincter, not a weak one that could result in incontinence (option 3). Hemorrhoids would occur only if severe drying out of the stool occurs and, thus, repeated need to strain to pass stool (option 4). **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 48-1.
2. **Answer:** 2. **Rationale:** The standard of practice in assisting older adults to maintain normal function of the gastrointestinal tract is regular ingestion of a well-balanced diet, adequate fluid intake, and regular exercise. If the bowel pattern is not regular with these activities, this abnormality should be reported. Stimulant laxatives can be very irritating and are not the preferred treatment for occasional constipation in older adults (option 2). In addition, a normal stool pattern for an older adult may not be daily elimination. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 48-3.
3. **Answer:** 4. **Rationale:** Small-volume enemas along with other preparations are used to prepare the client for this procedure. An oil retention enema is used to soften hard stool (option 1). Return flow enemas help expel flatus (option 2). Because of the risk of loss of fluid and electrolytes, high, large-volume enemas are seldom used (option 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 48-8.
4. **Answer:** 3. **Rationale:** An established stoma should be dark pink like the color of the buccal mucosa and is slightly raised above the abdomen. The skin under the appliance may remain pink or red for a while after the adhesive is pulled off. Feces from an ascending ostomy are very liquid, less so from a transverse ostomy, and more solid from a descending or sigmoid stoma. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 48-9.
5. **Answer:** 2. **Rationale:** Once the cause of diarrhea has been identified and corrected, the client should return to his or her previous elimination pattern. This is not an example of an allergy to the antibiotic but a common consequence of overgrowth of bowel organisms not killed by the drug (option 1). Antidiarrheal medications are usually prescribed according to the number of stools, not routinely around the clock (option 3). Increasing intake of soluble fiber such as oatmeal or potatoes may help absorb excess liquid and decrease the diarrhea, but insoluble fiber will not (option 4). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 48-6.
6. **Answer:** 2. **Rationale:** The client has assessment findings consistent with complications of surgery. Option 1: Irrigating the stoma is a dependent nursing action, and is also intervention without appropriate assessment. Option 3: Assessing the peristomal skin area is an independent action, but administering an antiemetic is an intervention without appropriate assessment. Antiemetics are generally ordered to treat immediate postoperative nausea, not several days postoperative. Option 4: Administering a bulk-forming laxative to a nauseated postoperative client is contraindicated. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 48-6.
7. **Answer:** 3. **Rationale:** This provides relief of postoperative flatus, stimulating bowel motility. Options 1, 2, and 4 manage constipation and do not provide flatus relief. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 48-8.
8. **Answer:** 3. **Rationale:** Blood in the upper GI tract is black and tarry. Option 1 can be a sign of malabsorption in an infant, option 2 is normal stool, and option 4 is characteristic of an obstructive condition of the rectum. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 48-2.
9. **Answer:** 1, 3, 4, and 5. **Rationale:** Option 1 is the most appropriate. The client is unable to decide when stool evacuation will occur. In option 3, client thoughts about self may be altered if unable to control stool evacuation. In option 4, the client may not feel as comfortable around others. In option 5, increased tissue contact with fecal material may result in impairment. Option 2 is more appropriate for a client with diarrhea. Incontinence is the inability to control feces of normal consistency. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 48-6.
10. **Answer:** 5. **Rationale:** Option 5 is a sigmoidostomy site. Option 1 is an ileostomy site, option 2 is ascending colostomy, option 3 is transverse colostomy, and option 4 is descending colostomy. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 48-9.

CHAPTER 49 Oxygenation

1. **Answer:** 4. **Rationale:** A bluish tinge to mucous membranes is called cyanosis. This is most accurate because it is what the nurse observes. The nurse can only observe signs and symptoms of hypoxia (option 1). More information is needed to validate this conclusion. Hypoxemia requires blood oxygen saturation data to be confirmed (option 2), and dyspnea is difficulty breathing (option 3). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 49-5.
2. **Answer:** 3. **Rationale:** Huff coughing helps keep the airways open and secretions mobilized. It is an alternative for clients who are unable to perform a normal forceful cough (e.g., postoperatively). Deep breathing and coughing should be performed at the same time; only at mealtimes is not sufficient (option 1). Extended forceful coughing fatigues the client, especially postoperatively (option 2). Diaphragmatic and pursed-lip breathing are techniques used for clients with obstructive airway disease (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 49-9.
3. **Answer:** 1. **Rationale:** Prior to starting the procedure, it is important to develop a means of communication by which the client can express pain or discomfort. The twill tape is not changed until after performing tracheostomy care (option 2).

Cleaning the incision should be done after cleaning the inner cannula (option 3). Checking the tightness of the ties and knot is done after applying new twill tape (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 49-11d.

4. **Answer:** 3. **Rationale:** Rotating the catheter prevents pulling of tissue into the opening on the catheter tip and side. Suction catheters may only be lubricated with water or water-soluble lubricant (petroleum jelly, e.g., Vaseline, has an oil base) (option 1). No suction should ever be applied while the catheter is being inserted because this can traumatize tissues (option 2). The client should be hyperoxygenated for only a few minutes before and after suctioning and this is generally limited to clients who are intubated or have a tracheostomy (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 49-9.
5. **Answer:** 1, 3, 4, and 5. **Rationale:** Respiratory function can be altered by conditions that affect a patent airway (option 1), the movement of air into or out of the lungs (option 5—a high temperature and pain can cause tachypnea), diffusion of oxygen and carbon dioxide between the alveoli and the pulmonary capillaries (option 3 where the blood loss causes decrease in hemoglobin, which carries oxygen), and the transport of oxygen and carbon dioxide via the blood to and from the tissue cells (option 4—heart failure decreases cardiac output). Option 2 is the definition of normal respiration. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 49-6.
6. **Answer:** 2. **Rationale:** The tube should be reconnected to the water seal as quickly as possible. Assisting the client back to bed (option 1) and assessing the client's lung sounds (option 3) are possible actions after the system is reconnected. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 49-9.
7. **Answer:** 1. **Rationale:** Anemia is a condition of decreased red blood cells and decreased hemoglobin. Hemoglobin is how the oxygen molecules are transported to the tissues. Option 2 would depend on where the infection is located. Option 3: A fractured rib would interrupt transport of oxygen from the atmosphere to the airways. Option 4: Damage to the medulla would interfere with neural stimulation of the respiratory system. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 49-7.
8. **Answer:** 3. **Rationale:** Respiratory difficulty related to a reclining position without other physical alterations is defined as orthopnea. **Cognitive Level:** Remembering. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Diagnosis. **Learning Outcome:** 49-5.
9. **Answer:** 4. **Rationale:** Glucocorticoids are prescribed because of their anti-inflammatory effect. Options 1, 2, and 3 are not achieved with glucocorticoids. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 49-9.
10. **Answer:** 1. **Rationale:** Postural drainage results in expectoration of large amounts of mucus. Clients sometimes ingest part of the secretions. The secretions may also produce an unpleasant taste in the oral cavity, which could result in nausea and vomiting. This procedure should be done on an empty stomach to decrease client discomfort. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 49-8.

CHAPTER 50 Circulation

1. **Answer:** 1. **Rationale:** Regular physical activity will help promote healthy cardiac functioning and will also promote tissue perfusion. With physical activity the heart muscle becomes more powerful and efficient, and the client has cardiovascular risk factors. Option 2: Improving tissue perfusion may also improve renal perfusion but it is not the primary goal. Option 3: Red, not white, blood cells carry oxygen. Option 4: Effective breathing and airway clearance focus primarily on the respiratory system. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 50-4.
2. **Answer:** 3, 1, 4, 2, and 5. **Rationale:** See sequence described on pages 1322–1323. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 50-1.
3. **Answer:** 3. **Rationale:** Capillary refill is an assessment of capillary blood flow and thus tissue perfusion. Symmetrical chest expansion (option 1) is an assessment of respiratory function; pursed-lip breathing (option 2) is a technique used to assist clients with obstructive lung diseases to keep alveoli open during respirations. Activity intolerance (option 4) can occur because of low cardiac output (e.g., heart failure). Activity tolerance would indicate adequate tissue perfusion. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 50-4.
4. **Answer:** 3 and 5. **Rationale:** Creatine kinase (CK) and troponin are enzymes that are released into the blood when there is hypoxia and myocardial damage. Option 1 reflects renal function. Option 2 reflects the number of red blood cells. Option 4 reflects level of atherosclerosis, which if increased reflects a risk for myocardial infarction and other cardiovascular diseases. Altered levels 1, 2, and 4 do not cause chest pain. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 50-4.
5. **Answer:** 3. **Rationale:** Very rapid heart rates do not allow adequate time for the ventricles to fill, causing cardiac output to fall. Option 1 is a normal response to exercise and does not reflect poor cardiac output. It could reflect poor cardiac output if the client was experiencing difficulty in breathing. Option 2 is a normal cardiac output of 4900 mL/min. The formula is $SV \times HR = CO$, which is about 5 L/min. Option 4 is incorrect because positive inotropic drugs (e.g., digoxin) increase contractility of the cardiac muscle and thus increase stroke volume, which increases cardiac output. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 50-1.
6. **Answer:** 3. **Rationale:** Because the clients would experience impaired tissue perfusion resulting in respiratory compensation, they are most likely to experience the sign or symptom of shortness of breath. The client with the MI will experience cardiac impairment resulting in decreased cardiac output as well as severe chest pain resulting in increased oxygen demand with decreased availability. Clients with heart failure will have decreased pumping ability of the cardiac muscle resulting in pulmonary congestion and decreased cardiac output. Clients with anemia have fewer RBCs to carry the oxygen to the tissues, resulting in hypoxia. Options 1 and 4 would be signs for the client with the MI. Option 2 is seen in heart failure. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 50-3.
7. **Answer:** 4. **Rationale:** The three cardinal signs of cardiac arrest are apnea, absence of a carotid or femoral pulse, and dilated pupils. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 50-5.
8. **Answer:** 1, 3, and 5. **Rationale:** Option 1: An example of impaired tissue perfusion is a decrease in arterial circulation in the legs related to atherosclerosis. Option 3: Examples of inadequate cardiac output are clients with MI, heart failure, or tachycardia. Option 5: Not enough blood is being pumped by the heart to meet the demands of the body. *Activity Intolerance*

is when the client does not have physiologic energy for ADLs. Common reasons can be anemias and heart failure. Options 2 and 4: Confusion and impaired sleep are not directly related to cardiovascular disease. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 50-4.

9. **Answer:** 2. **Rationale:** SCDs promote venous return from the legs to the heart. They inflate and deflate plastic sleeves wrapped around the legs to promote venous flow. The sequential inflation and deflation counteract blood stasis in the lower extremities. Option 1: Arterial flow is from the heart to the general circulation. Option 3: Afterload is related to the ventricles' ability to eject blood forward. These devices affect peripheral circulation. Option 4: There is no relationship between pain and the purpose of the devices. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 50-6.
10. **Answer:**

Cognitive Level: Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 50-1.

CHAPTER 51 Fluid, Electrolyte, and Acid–Base Balance

1. **Answer:** 2. **Rationale:** All other options are indicative of fluid volume excess. A client who has not eaten or drunk anything for several days would be experiencing fluid volume deficit. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcomes:** 51-4; 51-5.
2. **Answer:** 2. **Rationale:** Further assessment is needed to determine appropriate action. The husband and wife did supply the nurse with subjective assessment data; however, the laboratory results would provide important objective data. While the nurse may perform some of the interventions in options 1, 3, and 4, assessment is needed initially. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 51-8.
3. **Answer:** Hypertonic. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 51-1.
4. **Answer:** 2. **Rationale:** Because of the retention of CO_2, the clinical profile of respiratory acidosis includes decreased pH < 7.35, $PaCO_2 > 42$ mmHg, with varying levels of HCO_3 related to hypoventilation. Option 1 is respiratory alkalosis, which occurs because of blowing off of CO_2 resulting in a decreased level of acid and retention or production of bicarbonate, which in turn results in pH > 7.45, $PaCO_2 < 38$ mmHg, $HCO_3 > 26$ mEq/L related to hyperventilation. Option 3: Metabolic acidosis occurs because of a gain of hydrogen ions or a loss of HCO_3 with a pH < 7.35, normal $PaCO_2$ of 35–45 mmHg, and $HCO_3 < 22$ mEq/L, often caused by diarrhea, bicarbonate infusion, or retention related to kidney failure. Option 4: Metabolic alkalosis is caused by gain of bicarbonate or loss of hydrogen ions related to vomiting, gastric suction, or loss of upper gastrointestinal secretions by various other methods. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcomes:** 51-2; 51-5.
5. **Answer:** 1, 3, and 5. **Rationale:** Options 1, 3, and 5 relate to decreased fluid volume. The data indicate an actual problem, which excludes option 2. Option 4 relates more to increased fluid volume. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 51-6.
6. **Answer:** 4. **Rationale:** Salt substitutes contain potassium. The client can still use it within reason. Option 1: Avocado is higher in potassium than most foods. Option 2: Hypokalemia can potentiate digoxin toxicity and checking the pulse will help the client avoid this. Option 3: It is important to take potassium with food to avoid gastric upset. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcomes:** 51-7; 51-8.
7. **Answer:** 2. **Rationale:** Sodium contributes to the function of neural tissue. Because calcium contributes to the function of voluntary muscle contraction, options 1 and 4 are more appropriate for calcium imbalances. Option 3: Because potassium and calcium contribute to cardiac function, irregular pulse is more likely to be associated with those alterations. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 51-5.
8. **Answer:** 2. **Rationale:** Because of CO_2 retention the $PaCO_2$ is elevated. CO_2 is involved in production of acid, which will result in a decreased pH. HCO_3 will vary. Option 1: Metabolic acidosis involves a loss of bicarbonate, but no retention of CO_2. Option 3: Metabolic alkalosis involves a loss of acid or retention of HCO_3, but no retention of CO_2. Option 4: Respiratory alkalosis involves a loss of CO_2 resulting in an increased pH. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 51-5.
9. **Answer:** 4. **Rationale:** The major clinical signs and symptoms of hypocalcemia are due to increased neuromuscular activity and not the renal, cardiac, or GI systems. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 51-8.
10. **Answer:** 2, 4, and 5. **Rationale:** Options 1 and 3 relate to hypermagnesemia. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcomes:** 51-4; 51-5.

Glossary

24-hour food recall client recall of all the food and beverages consumed during a typical 24-hour period

Abdominal paracentesis a procedure to obtain a specimen of ascetic fluid for laboratory study and to relieve pressure on the abdominal organs due to the presence of excess fluid

Absorption the process by which a drug passes into the bloodstream

Abusive head trauma classified as injuries caused by violent shaking of the infant that causes whiplash and results in brain injury

Accommodation a process of change whereby cognitive processes mature sufficiently to allow an individual to solve problems that were previously unsolvable

Accountability the ability and willingness to assume responsibility for one's actions and to accept the consequences of one's behavior

Accountable care organizations (ACOs) characterized by a payment and care delivery model that ties provider reimbursements to quality metrics and reductions in the total cost of care for an assigned population of clients

Acculturation the involuntary process that occurs when individuals adapt to or borrow traits from another culture

Acid a substance that releases hydrogen ions (H^+) in solution

Acidosis a condition that occurs with increases in blood carbonic acid or with decreases in blood bicarbonate; blood pH below 7.35

Acquired immunity *see* Passive immunity

Action stage occurs when an individual actively implements behavioral and cognitive strategies to interrupt previous behavior patterns and adopt new ones; this stage requires a great commitment of time and energy

Active euthanasia actions that directly bring about the client's death with or without consent

Active immunity a resistance of the body to infection in which the host produces its own antibodies in response to natural or artificial antigens

Active ROM (range-of-motion) exercises isotonic exercises in which the client independently moves each joint in the body through its complete range of movement, maximally stretching all muscle groups within each plane, over the joint

Active transport the movement of solutes across cell membranes from a less concentrated solution to a more concentrated one

Activity-exercise pattern refers to an individual's pattern of exercise, activity, leisure, and recreation

Activity theory the best way to age is to stay active physically and mentally

Activity tolerance the type and amount of exercise or daily activities an individual is able to perform

Actual loss can be recognized by others

Acupressure a technique that uses the fingers to apply pressure to specific points along meridians throughout the body

Acupuncture a form of healing in which the therapist applies needles to stimulate specific sites of the body

Acute confusion abrupt onset of confusion that has a reversible cause; also called *delirium*

Acute hemolytic transfusion reaction condition caused by the transfusion of ABO- or Rh- incompatible blood, which causes destruction of the transfused RBCs and subsequent risk of kidney damage or failure

Acute illness typically characterized by severe symptoms of relatively short duration

Acute infections those that generally appear suddenly or last a short time

Acute pain pain that lasts only through the expected recovery period (as opposed to chronic)

Adaptation the process of modifying to meet new, changing, or different conditions

Adaptive mechanisms *see* Defense mechanisms

Addiction chronic, relapsing, treatable disease influenced by genetic, developmental, and environmental factors

Adherence the extent to which an individual's behavior (for example, taking medications, following diets, or making lifestyle changes) coincides with medical or health advice; commitment or attachment to a regimen

Adjuvant medication that is not classified as a pain medication and that may reduce pain alone or in combination with other analgesics, relieve other discomforts, potentiate the effect of pain medications, or reduce the pain medication's side effects

Adolescence the period during which an individual becomes physically and psychologically mature and acquires a personal identity

Adolescent growth spurt the period during puberty when sudden and dramatic physical changes occur

Adult day care a day care center that provides health and social services to older adults

Advance healthcare directives a variety of legal and lay documents that allow individuals to specify aspects of care they wish to receive should they become unable to make or communicate their preferences

Adventitious breath sounds abnormal breath sounds that occur when air passes through narrowed airways or airways filled with fluid or mucus, or when pleural linings are inflamed

Adverse effects severe side effects that may justify the discontinuation of a drug

Advocate individual who pleads the cause of another or argues or pleads for a cause or proposal

Aerobic growing only in the presence of oxygen

Aerobic exercise any activity during which the body takes in more or an equal amount of oxygen than it expends

Aesthetic knowing providing care and meeting the needs of clients through creativity and style

Afebrile absence of a fever

Affective domain known as the "feeling" domain, relates to the client's attitudes, interests, attention, awareness, and values

Afterload the resistance against which the heart must pump to eject blood into the circulation

Ageism deep and profound prejudice in American society against older adults

Ages & Stages Questionnaires (ASQ) includes 19 age-specific surveys in which parents are asked about the developmental skills observed in ages 1 month to 5 1/2 years to assist healthcare professionals in identifying children who are at risk for social and emotional developmental delays

Agglutinins specific antibodies formed in the blood

Agglutinogens a substance that acts as an antigen and stimulates the production of agglutinins

Agnostic an individual who doubts the existence of God or a supreme being or believes the existence of God has not been proved

Agonist a drug that interacts with a receptor to produce a response

Airborne precautions used for clients known to have or suspected of having serious illnesses transmitted by airborne droplet nuclei smaller than 5 microns

Alarm reaction the initial reaction of the body to stress, which alerts the body's defenses

Alexian Brothers religious order that organized care for victims of the Black Plague in the 14th century in Germany and established hospitals and provided nursing care in the 19th century

Algor mortis the gradual decrease of the body's temperature after death

Alkalosis a condition that occurs with increases in blood bicarbonate or decreases in blood carbonic acid; blood pH above 7.45

Allopathic medicine term used to describe Western medical practice

Alopecia the loss of scalp hair (baldness) or body hair

Alternative medicine an unrelated group of nonorthodox practices, often with explanatory systems that do not follow conventional biomedical explanations

Alzheimer's disease disease that involves progressive dementia, memory loss, and inability to care for self

Amblyopia reduced visual acuity in one eye

Ambulation the act of walking

Ampule a glass container usually designed to hold a single dose of a drug

Anabolism a process in which simple substances are converted by the body's cells into more complex substances (e.g., building tissue, positive nitrogen balance)

Anaerobic growing only in the absence of oxygen

Anaerobic exercise involves activity in which the muscles cannot draw out enough oxygen from the bloodstream; used in endurance training

Anal stimulation stimulation applied to anus for sexual pleasure

Anaphylactic reaction a severe allergic reaction that usually occurs immediately after the administration of a drug

Andragogy the art and science of helping adults learn

Androgyny belief that most characteristics and behaviors are human qualities and not limited to a gender

Anemia a condition in which the blood is deficient in red blood cells or hemoglobin

Anger an emotional state consisting of a subjective feeling of animosity or strong displeasure

Angiography a diagnostic procedure enabling x-ray visual examination of the vascular system after injection of a radiopaque dye

Angle of Louis the junction between the body of the sternum and the manubrium; the starting point for locating the ribs anteriorly

Animal-assisted therapy the use of specifically selected animals as a treatment modality in health and human service settings

Anions ions that carry a negative charge; includes chlorine (Cl^-), bicarbonate (HCO_3^-), phosphate (HPO_4^{2-}), and sulfate (SO_4^-)

Ankylosed permanently immobile joints

Anorexia loss of appetite

Anorexia nervosa a disease characterized by a prolonged inability or refusal to eat, rapid weight loss, and emaciation in individuals who continue to believe they are fat

Anoscopy visual examination of the anal canal using an anoscope (a lighted instrument)

Answer (legal) a written response made by a defendant

Antagonist drug that inhibits cell function by occupying the drug's receptor sites

Antibodies part of the body's plasma proteins that defend primarily against the extracellular phases of bacterial and viral infections; also called *immunoglobulins*

Anticipatory grief grief experienced in advance of an event

Anticipatory loss the experience of loss before the loss actually occurs

Antigen a substance capable of inducing the formation of antibodies

Antihelix the anterior curve of the auricle's upper aspect

Antiseptics an agent that inhibits the growth of some microorganisms

Anuria the failure of the kidneys to produce urine, resulting in a total lack of urination or output of less than 100 mL/day in an adult

Anxiety a state of mental uneasiness, apprehension, or dread producing an increased level of arousal caused by an impending or anticipated threat to self or significant relationships

Apgar scoring system a scoring system to assess newborn babies

Aphasia any defects in or loss of the power to express oneself by speech, writing, or signs, or to comprehend spoken or written language due to disease or injury of the cerebral cortex

Apical pulse a central pulse located at the apex of the heart

Apical–radial pulse measurement of the apical and radial pulse simultaneously

Apnea a complete absence of respirations

Apocrine glands sweat glands located largely in the axillae and anogenital areas; they begin to function at puberty under the influence of androgens

Approximated closed tissue surfaces

Aromatherapy therapeutic use of essential oils of plants in which odor or fragrance plays an important part

Arrhythmia an irregular heart rhythm

Arterial blood gases specimen of arterial blood that assesses oxygenation, ventilation, and acid–base status

Arterial blood pressure the measure of the pressure exerted by the blood as it pulsates through the arteries

Arteriosclerosis a condition in which the elastic and muscular tissues of the arteries are replaced with fibrous tissue

Ascites a large amount of fluid accumulation in the abdominal cavity

Asepsis freedom from infection or infectious material

Asphyxiation lack of oxygen due to interrupted breathing

Aspiration withdrawal of fluid that has abnormally collected (e.g., pleural cavity, abdominal cavity) or to obtain a specimen (e.g., cerebrospinal fluid)

Assault an attempt or threat to touch another individual unjustifiably

Assessing the process of collecting, organizing, validating, and recording data (information) about a client's health status

Assimilation the process by which an individual develops a new cultural identity and becomes like the members of the dominant culture

Assisted living facility with various degrees of personal care assistance designed to meet the needs of an older adult

Assisted suicide a form of active euthanasia in which clients are given the means to kill themselves

Astigmatism an uneven curvature of the cornea that prevents horizontal and vertical light rays from focusing on the retina

Atelectasis collapse of the air sacs

Atheist one without belief in a deity

Atherosclerosis buildup of fatty plaque within the arteries

Atria two upper hollow chambers of the heart

Atrioventricular (AV) node conduction pathways that slightly delay transmission of the impulse from the atria to the ventricles of the heart

Atrioventricular (AV) valves between the atria and ventricles of the heart, the tricuspid valve on the right and the bicuspid or mitral valve on the left

Atrophy wasting away; decrease in size of organ or tissue (e.g., muscle)

Attachment an essential human need for lasting, strong, emotional bonds with others

Attentive listening listening actively, using all senses, as opposed to listening passively with just the ear

Attitudes mental stance that is composed of many different beliefs; usually involving a positive or negative judgment toward an individual, object, or idea

Audit examination or review of records

Auditory related to or experienced through hearing

Auricle flap of the ear; also called *pinna*

Auscultation the process of listening to sounds produced within the body, such as with the use of a stethoscope that amplifies sounds and conveys them to the nurse's ears

Auscultatory gap the temporary disappearance of sounds normally heard over the brachial artery when the sphygmomanometer cuff pressure is high, followed by the reappearance of sounds at a lower level

Authoritarian leader the individual who makes decisions for the group

Authority the power given by an organization to direct the work of others; the right to act

Autoantigen an antigen that originates in an individual's own body

Autocratic leader *see* Authoritarian leader

Automaticity an electrical impulse and contraction independent of the nervous system and generated by the cardiac muscle

Autonomy the state of being independent and self-directed, without outside control, to make one's own decisions

Autopsy an examination of the body after death to determine the cause of death and to learn more about a disease process; also called *postmortem examination*

Awareness the ability to perceive environmental stimuli and body reactions and to respond appropriately through thought and action

Ayurveda Indian system of medicine where illness is viewed as a state of imbalance among the body's systems

Baby boomers generation that includes those born in years 1945–1964

Bacteremia bacteria in the blood

Bacteria the most common infection-causing microorganisms

Balance a state of equilibrium in which opposing forces counteract each other

Bandage a strip of cloth used to wrap some part of the body

Basal metabolic rate (BMR) the rate of energy utilization in the body required to maintain essential activities such as breathing

Base of support the foundation on which an object rests

Bases (alkalis) have low hydrogen ion concentration and can accept hydrogen ions in solution

Battery (legal) the willful or negligent touching of an individual (or the individual's clothes or even something the individual is carrying), which may or may not cause harm

Bedpan a receptacle for urine and feces

Bedrest strict confinement to bed (complete bedrest), or the client may be allowed to use a bedside commode or have bathroom privileges

Behaviorist theory includes the identification of what is to be taught and the shaping of behavior through positive and negative reinforcement

Beliefs interpretations or conclusions that one accepts as true

Beneficence the moral obligation to do good or to implement actions that benefit clients and their support people

Bereavement a subjective response of an individual who has experienced the loss of a significant other through death

Bevel the slanted part at the tip of a needle

Binder a type of bandage applied to large body areas (abdomen or chest) that is designed for a specific body part (e.g., arm sling); used to provide support

Bioelectromagnetics science that studies how living organisms interact with electromagnetic fields

Bioethics ethical rules or principles that govern right conduct concerning life

Biofeedback a stress management technique that brings under conscious control bodily processes normally thought to be beyond voluntary command

Biological rhythms in humans, these rhythms, such as the circadian rhythm, are controlled from within the body and synchronized with environmental factors, such as light and darkness

Biomedical health belief *see* Scientific health belief

Biomedicine term used to describe Western medical practice

Biopsy removal and examination of tissue

Biotransformation process by which a drug is converted to a less active form; also called *detoxification* or *metabolism*

Bladder retraining client postpones voiding, resists or inhibits the sensation of urgency, and voids according to a timetable rather than according to the urge to void

Blanch test a test during which the client's fingertip is temporarily pinched to assess capillary refill and peripheral circulation

Bloodborne pathogens potentially infectious organisms that are carried in and transmitted through blood or materials containing blood

Blood chemistry a number of tests performed on blood serum (the liquid portion of the blood)

Blood pressure (BP) the force exerted on arterial walls by blood flowing within the vessel

Blood urea nitrogen (BUN) a measure of blood level of urea, the end product of protein metabolism

Body image how an individual perceives the size, appearance, and functioning of his or her body and its parts

Body mass index (BMI) indicates whether weight is appropriate for height

Body temperature the balance between the heat produced by the body and the heat lost from the body

Boomerang kids slang term used for young adults who move back into their parents' homes after an initial period of independent living

Bottle mouth syndrome describes the decay of an infant's teeth caused by constant contact with sweet liquid from a bottle

Boundary the real or imaginary lines that differentiate one system from another system or a system from its environment

Bowel incontinence loss of voluntary ability to control fecal and gaseous discharges through the anal sphincter; also called *fecal incontinence*

Bradycardia abnormally slow pulse rate, less than 60 beats per minute

Bradypnea abnormally slow respiratory rate, usually less than 10 respirations per minute

Brand name name of the drug given by the drug manufacturer; also called the *trade name*

Breach of duty a standard of care that is expected in the specific situation but that the nurse did not observe; this is the failure to act as a reasonable, prudent nurse under the circumstances

Bruit a blowing or swishing sound created by turbulence of blood flow

Buccal a medication (e.g., a tablet) that is held in the mouth against the mucous membranes of the cheek until the drug dissolves

Buffers prevent excessive changes in pH by removing or releasing hydrogen ions

Bulimia an uncontrollable compulsion to eat large amounts of food and then expel it by self-induced vomiting or by taking laxatives

Bullying repeated, health-harming mistreatment of one or more individuals by one or more perpetrators

Bundle of His the right and left bundle branches of the ventricular conduction pathways

Burden of proof the duty of proving an assertion

Bureaucratic leader does not trust self or others to make decisions and instead relies on the organization's rules, policies, and procedures to direct the group's work efforts

Burn results from excessive exposure to thermal, chemical, electric, or radioactive agents

Burnout a complex syndrome of behaviors that can be likened to the exhaustion stage of the general adaptation syndrome; an overwhelming feeling that can lead to physical and emotional depletion, a negative attitude and self-concept, and feelings of helplessness and hopelessness

Calculi renal stones

Callus a thickened portion of the skin

Caloric value the amount of energy that nutrients or foods supply to the body

Calorie a unit of heat energy

Cancer-related pain may result from the direct effects of the disease and its treatment, such as radiation or chemotherapy

Cannula a tube with a lumen (channel) that is inserted into a cavity or duct and is often fitted with a trocar during insertion for abdominal paracentesis; the part of the needle that is attached to the hub; also called a *shaft*

Carbon monoxide an odorless, colorless, tasteless gas that is very toxic

Cardiac output (CO) the amount of blood ejected by the heart with each ventricular contraction

Caregiver a role that has traditionally included those activities that assist the client physically and psychologically

Caregiver burden responses to long-term stress, such as chronic fatigue, sleeping difficulties, and high blood pressure, in family members who undertake the care of an individual in the home for a long period

Caregiver role strain physical, emotional, social, and financial burdens that can seriously jeopardize the caregiver's own health and well-being

Caries tooth cavities

Caring intentional action that conveys physical and emotional security and genuine connectedness with another individual or group of individuals

Caring practice nursing care that includes connection, mutual recognition, and involvement

Carminative an agent that promotes the passage of flatus from the colon

Carrier an individual or animal that harbors a specific infectious agent and serves as a potential source of infection, yet does not manifest any clinical signs of disease

Case management a method for delivering nursing care in which the nurse is responsible for a caseload of clients across the healthcare continuum

Case manager a nurse who works with the multidisciplinary healthcare team to measure the effectiveness of the case management plan and monitor outcomes

Catabolism a process in which complex substances are broken down into simpler substances (e.g., breakdown of tissue)

Cataract an opacity of the eye lens or its capsule that blocks light rays

Cathartics drugs that induce defecation

Cations ions that carry a positive charge; includes sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), and magnesium (Mg^{2+})

Causation a fact that must be proven that the harm occurred as a direct result of the nurse's failure to follow the standard of care and the nurse could have (or should have) known that failure to follow the standard of care could result in such harm

CAUTI (catheter-associated urinary tract infection) a urinary tract infection that is associated with an indwelling urinary catheter that has been in place for more than 2 calendar days

Cell-mediated defenses *see* Cellular immunity

Cellular immunity occurs through the T-cell system; also known as *cell-mediated defenses*

Center of gravity the point at which all of the mass (weight) of an object is centered

Central vascular access device defined by the location of the catheter tip in a central vein, in the lower one-third of the superios vena cava, above the right atrium

Cephalocaudal proceeding in the direction from head to toe

Cerebral death occurs when the cerebral cortex is irreversibly destroyed; also called *higher brain death*

Cerumen earwax

Change process of making something different from what it was

Change agent individual (or group) who initiates change or who assists others in making modifications in themselves or in the system

Change-of-shift report a report given to nurses on the next shift

Charismatic leader characterized by an emotional relationship between the leader and the group members; personality of the leader evokes strong feelings of commitment to both the leader and the leader's cause and beliefs

Chart a formal, legal document that provides evidence of a client's care

Charting the process of making an entry on a client record

Charting by exception (CBE) a documentation system in which only significant findings or exceptions to norms are recorded

Chemical name the name by which a chemist knows a drug; describes the constituents of the drug precisely

Chemical restraints medications used to control socially disruptive behavior

Chiropractic from the Greek meaning "done by hand"; involves adjustments of the spine and joints and is grounded in the assumption that maintaining the alignment of the spine and joints facilitates the flow of energy throughout the body, including the nervous, circulatory, respiratory, gastrointestinal, and limbic systems

Cholesterol a fatlike substance that is both produced by the body and found in foods of animal origin

Chronic confusion progressive loss of cognitive function that has symptoms that are gradual and irreversible; also called *dementia*

Chronic illness illness that lasts for an extended period of time, usually longer than 6 months

Chronic infection infection that occurs slowly, over a very long period, and may last months or years

Chronic pain prolonged pain, usually recurring or persisting over 6 months or longer, that interferes with functioning

Chyme contents of the colon

Circulating immunity *see* Humoral immunity

Circulating nurse coordinates activities and manages client care by continually assessing client safety, aseptic practice, and the environment (e.g., temperature, humidity, and lighting); with the scrub nurse, is responsible for accounting for all sponges, needles, and instruments at the close of surgery

Civil actions deals with the relationship between individuals in society

Civil law the body of law that deals with relationships among private individuals; also known as *private law*

Clara Barton a schoolteacher who volunteered as a nurse during the Civil War. Most notably, she organized the American Red Cross, which linked with the International Red Cross when the U.S. Congress ratified the Geneva Convention in 1882

Clean free of potentially infectious agents

Clean-catch specimen urine specimens for urine culture; also called *midstream urine specimen*

Clean voided specimen urine specimens for routine urinalysis

Cleansing bath a bath given for hygienic purposes

Client an individual who engages the advice or services of another who is qualified to provide this service

Client advocate an individual who acts to protect the client

Client record *see* Chart

Climacteric the point in development when reproduction capacity in the female terminates (menopause) and the sexual activity of the male decreases (andropause)

Clinical decision support systems electronic forms of nursing tools such as charts, templates, algorithms, and others, which incorporate evidence from the literature into particular client situations in order to guide care planning

Clinical judgment decision-making process to ascertain the right nursing action to be implemented at the appropriate time in the client's care

Clinical reasoning cognitive process that uses thinking strategies to gather, analyze, and evaluate the relevance of client information, and

decide on possible nursing actions to improve the client's physiologic and psychosocial outcomes

Closed awareness a type of awareness in which the client is unaware of impending death

Closed questions restrictive question requiring only a short answer

Closed system does not exchange energy, matter, or information with its environment; it receives no input from the environment and gives no output to the environment

Closed wound drainage system consists of a drain connected to either an electric suction or a portable drainage suction

Clubbing elevation of the proximal aspect of the nail and softening of the nail bed

Coanalgesic a medication that is not classified as a pain medication but has properties that may reduce pain alone or in combination with other analgesics, relieve other discomforts, potentiate the effect of pain medication, or reduce the pain medication's side effects

Cochlea a seashell-shaped structure found in the inner ear; essential for sound transmission and hearing

Code of ethics a formal statement of a group's ideals and values; a set of ethical principles shared by members of a group, reflecting their moral judgments and serving as a standard for professional actions

Cognitive development refers to the manner in which individuals learn to think, reason, and use language

Cognitive domain the "thinking" domain, includes six intellectual abilities and thinking processes beginning with remembering, understanding, and applying to analyzing, evaluating, and creating

Cognitive processes the thinking processes based on the knowledge of aspects of client care

Cognitive skills intellectual skills that include problem solving, decision making, critical thinking, and creativity

Cognitive theory recognition of developmental levels of learners, and acknowledgments of the learner's motivation and environment

Coinsurance an insurance plan in which the client pays a percentage of the payment and some other group (e.g., employer, government) pays the remaining percentage

Coitus penile–vaginal intercourse

Collaboration a collegial working relationship with another healthcare provider in the provision of client care

Collaborative care plans *see* Critical pathways

Collaborative interventions actions the nurse carries out in collaboration with other health team members, such as physical therapists, social workers, dietitians, and physicians

Collagen a protein found in connective tissue; a whitish protein substance that adds tensile strength to a wound

Colloid osmotic pressure holds water in plasma, and when necessary pulls water from the interstitial space into the vascular compartment to maintain vascular volume; also called *oncotic pressure*

Colloids substances such as large protein molecules that do not readily dissolve into true solutions

Colonization the presence of organisms in body secretions or excretions in which strains of bacteria become resident flora but do not cause illness

Colonoscopy visual examination of the interior of the colon with a colonoscope

Colostomy a temporary or permanent opening into the colon (large bowel) to divert and drain fecal material

Commode a portable chair with a toilet seat and a receptacle underneath that can be emptied; often used for the adult client who is able to get out of bed but is unable to walk to the bathroom

Common law the body of principles that evolves from court decisions

Communicable disease a disease that can spread from one individual to another

Communication a two-way process involving the sending and receiving of messages

Communicator a nurse identifies client problems and then communicates them verbally or in writing to other members of the health team

Community a collection of individuals who share some attribute of their lives

Community-based healthcare (CBHC) a system that provides health-related services within the context of individuals' daily lives; that is, in places where individuals spend their time in the community

Community-based nursing (CBN) nursing care directed toward a specific population or group within the community; primary, secondary, or tertiary care may be provided to individuals or groups

Community health nursing the synthesis of nursing and public health practice as applied to promoting and preserving the health of populations

Community nursing centers (CNCs) provide primary care to specific populations and are staffed by nurse practitioners and community health nurses

Comparative analysis involves assessing study findings for their implementation potential

Compensation defense mechanism in which an individual substitutes an activity for one that he or she would prefer doing or cannot do

Compensatory counterbalancing

Complaint (legal) a document filed by a plaintiff

Complementary medicine *see* Alternative medicine

Complete blood count (CBC) specimens of venous blood; includes hemoglobin and hematocrit measurements, erythrocyte (RBC) count, leukocyte (WBC) count, red blood cell indices, and a differential white cell count

Complete proteins proteins that contain all of the essential amino acids as well as many nonessential ones

Compliance in reference to the arteries, their ability to contract and expand

Complicated grief pathologic grief; exists when coping strategies are maladaptive

Compress a moist gauze dressing applied frequently to an open wound, sometimes medicated

Compromised host any individual at increased risk for an infection

Computed tomography (CT) a painless, noninvasive x-ray procedure that has the unique capability of distinguishing minor differences in the density of tissues

Computer-based patient records (CPRs) electronic client data retrievable by caregivers, administrators, accreditors, and other individuals who require the data

Computer literacy the knowledge and ability to use computers or technology

Concept map a visual tool in which ideas or data are enclosed in circles or boxes of some shape and relationships between these are indicated by connecting lines or arrows

Concept mapping technique that uses a graphic depiction of nonlinear and linear relationships to represent critical thinking

Concurrent audit evaluation of a client's healthcare while the client is still receiving care from the agency

Conduction the transfer of heat from one molecule to another in direct contact

Conductive hearing loss the result of interrupted transmission of sound waves through the outer and middle ear structures

Confidentiality any information a participant relates will not be made public or available to others without the participant's consent

Congruent communication occurs when the verbal and nonverbal aspects of the message match

Conjunctivitis inflammation of the bulbar and palpebral conjunctiva

Conscious sedation a minimal depression of level of consciousness during which the client retains the ability to consciously maintain a patent airway and respond appropriately to verbal and physical stimuli

Consequence-based (teleological) theories the ethics of judging whether an action is moral

Constant fever a state in which the body temperature fluctuates minimally but always remains above normal

Constipation passage of small, dry, hard stool or passage of no stool for a period of time

Consumer an individual, a group of individuals, or a community that uses a service or commodity

Contact precautions used for clients known or suspected to have serious illnesses easily transmitted by direct client contact or by contact with items in the client's environment (GI, respiratory, skin or wound infections, etc.)

Contemplation stage stage in which an individual acknowledges having a problem, seriously considers changing a specific behavior, actively gathers information, and verbalizes plans to change the behavior in the near future

Content analysis data analysis that involves searching for themes and patterns in a research study that uses a qualitative approach

Continuing education (CE) formalized experiences designed to enlarge the knowledge or skills of practitioners

Continuity of care the coordination of healthcare services by healthcare providers for clients moving from one healthcare setting to another and between and among healthcare professionals

Continuity theory individuals maintain their values, habits, and behavior in old age

Contract a written or verbal agreement between two or more individuals to do or not do some lawful act

Contractility the inherent ability of cardiac muscle fibers to shorten or contract

Contract law the enforcement of agreements among private individuals or the payment of compensation for failure to fulfill the agreement

Contractual obligations duty of care established by the presence of an expressed or implied contract

Contractual relationships vary among practice settings; may be as an independent or employer–employee relationship

Contracture permanent shortening of a muscle

Convection the dispersion of heat by air currents

Conventional medicine term used to describe Western medical practice

Coordinating the process of ensuring that plans are carried out and evaluating outcomes

Coping dealing with change

Coping mechanism *see* Coping strategy

Coping strategy a natural or learned way of responding to a changing environment or specific problem or situation

Core self-concept the beliefs and images that are most vital to an individual's identity

Core temperature the temperature of the deep tissues of the body (e.g., abdominal cavity, pelvic cavity). When measured orally, the average body temperature of an adult is between 36.7°C and 37°C (98°F and 98.6°F)

Corn a conical, circular, painful, raised area on the toe or foot

Coronary arteries a network of vessels known as the coronary circulation

Coroner a physician who is authorized by the county or other government agency to determine causes of deaths under unusual circumstances

Costal (thoracic) breathing movement of the chest upward and outward

Cost–benefit analysis involves consideration of the potential risks and benefits of both implementing a change based on a study's findings and not implementing a change

Counseling the process of helping a client to recognize and cope with stressful psychologic or social problems, to develop improved interpersonal relationships, and to promote personal growth

Countershock phase second part of the alarm reaction in which the changes the body experienced during the shock phase are reversed

C-reactive protein (CRP) screening test for the inflammatory process of acute myocardial infarction (AMI)

Creatine kinase (CK) enzyme that is released into the blood during a myocardial infarction

Creatinine a nitrogenous waste that is excreted in the urine

Creatinine clearance test that uses 24-hour urine and serum creatinine levels to determine the glomerular filtration rate, a sensitive indicator of renal function

Creativity thinking that results in the development of new ideas and products

Credentialing the process of determining and maintaining competence in practice; includes licensure, registration, certification, and accreditation

Credé's maneuver manual exertion of pressure on the bladder to force urine out

Crepitation palpable or audible crackling or grating sensation produced by joint motion and frequently experienced in joints that have suffered repeated trauma over time

Crime an act committed in violation of public (criminal) law and punishable by a fine and/or imprisonment

Criminal actions deal with disputes between an individual and the society as a whole

Criminal law deals with actions against the safety and welfare of the public

Crisis intervention a short-term helping process of assisting clients to work through a crisis to its resolution and restore their precrisis level of functioning

Critical analysis a set of questions one can apply to a particular situation or idea to determine essential information and ideas and discard superfluous information and ideas

Critical pathways multidisciplinary guidelines for client care based on specific medical diagnoses designed to achieve predetermined outcomes

Critical thinking a cognitive process that includes creativity, problem solving, and decision making

Critique to critically read and evaluate research articles

Cross-contamination the movement of microorganisms from one client to another

Cross-dressing dressing in clothing of the opposite sex

Crystalloids salts that dissolve readily into true solutions

Cues any piece of information or data that influences decisions

Cultural broker an individual, such as an interpreter, who engages both healthcare provider and client effectively and efficiently in accessing the nuances and hidden sociocultural assumptions embedded in each other's language

Cultural care deprivation lack of culturally assistive, supportive, or facilitative acts

Cultural competence provision of healthcare across cultural boundaries that takes into account the context in which the client lives, as well as the situations in which the client's health problems arise

Cultural deprivation *see* Cultural care deprivation

Culturally responsive care care that is centered on the client's cultural point of view and integrates the client's values and beliefs into the plan of care

Culture a worldview and set of traditions used and transmitted from generation to generation by a particular group; includes related attitudes and institutions

Cultures laboratory cultivations of microorganisms in a special growth medium

Cumulative effect the increasing response to repeated doses of a drug that occurs when the rate of administration exceeds the rate of metabolism or excretion

Curanderismo cultural healing tradition found in Latin America that uses Western medicine beliefs, treatments, and practices at three levels of care: material level, spiritual level, and mental level

Cyanosis a bluish tinge of skin color

Cystoscope a lighted instrument used to visualize the interior of the urinary bladder

Cystoscopy visual examination of the urinary bladder with a cystoscope

Dacryocystitis inflammation of the lacrimal sac

Damages if professional negligence caused an injury, the nurse is held liable for compensation in the form of damages

Dandruff a diffuse scaling of the scalp, often accompanied by itching

Data information

Database all information about a client, includes nursing health history and physical assessment, physician's history, physical examination, and laboratory and diagnostic test results

Data warehousing the accumulation of large amounts of data that are stored over time

Debridement removal of necrotic material

Decision (legal) outcome made by a judge

Decode to relate the message perceived to the receiver's storehouse of knowledge and experience and to sort out the meaning of the message

Deductive reasoning making specific observations from a generalization

Defamation (legal) a communication that is false, or made with careless disregard for the truth, and results in injury to the reputation of another

Defecation expulsion of feces from the anus and rectum

Defendant (legal) individual against whom a plaintiff files a complaint

Defense mechanisms methods the ego uses to fulfill the needs of the id in a socially acceptable manner; also called *adaptive mechanism*

Defining characteristics client signs and symptoms that must be present to validate a nursing diagnosis

Dehiscence the partial or total rupturing of a sutured wound; usually involves an abdominal wound in which the layers below the skin also separate

Dehydration insufficient fluid in the body

Delegation "allowing a delegate to perform a specific nursing activity, skill, or procedure that is beyond the delagatee's traditional role and not routinely performed. This applies to licensed nurses as well as UAP" (NCSBN, 2016, p.6).

Delirium abrupt onset of confusion that has a reversible cause; also called *acute confusion*

Demand feeding the feeding of a child when the child is hungry

Dementia progressive loss of cognitive function that has symptoms that are gradual and irreversible; also called *chronic confusion*

Democratic leader encourages group discussion and decision making

Denver Developmental Screening Test (DDST-II) a screening test used to assess children from birth to 6 years of age

Dependent functions with regard to medical diagnoses, physician-prescribed therapies and treatments nurses are obligated to carry out

Dependent interventions activities carried out on the orders or supervision of a licensed physician or other healthcare provider authorized to write orders for nurses

Dependent variable the behavior, characteristic, or outcome that the researcher wishes to explain or predict

Depression an extreme feeling of sadness, despair, dejection, lack of worth, or emptiness

Descriptive statistics procedures that summarize large volumes of data; used to describe and synthesize data, showing patterns and trends

Desired effect *see* Therapeutic effect

Desire phase part of the response cycle, which starts in the brain, with conscious sexual desires

Detoxification the belief that physical impurities and toxins must be cleared from the body to achieve better health

Detrusor muscle the smooth muscle layers of the bladder

Development an individual's increasing capacity and skill in functioning, related to growth

Developmental stage level of achievement for a particular segment of an individual's life

Developmental task skill or behavior pattern learned during stages of development

Diagnosis a statement or conclusion concerning the nature of some phenomenon

Diagnosis-related groups (DRGs) a Medicare payment system to hospitals and physicians that establishes fees according to diagnosis

Diaphragmatic (abdominal) breathing breathing that involves the contraction and relaxation of the diaphragm, as observed by the movement of the abdomen

Diarrhea defecation of liquid feces and increased frequency of defecation

Diastole in measuring blood pressure, the period during which the ventricles relax

Diastolic pressure the pressure of the blood against the arterial walls when the ventricles of the heart are at rest

Diet history a comprehensive assessment of a client's food intake that involves an extensive interview by a nutritionist or dietitian

Differentiated practice a system in which the best possible use of nursing personnel is based on their educational preparation and resultant skill sets

Diffusion the mixing of molecules or ions of two or more substances as a result of random motion

Directing a management function that involves communicating the task to be completed and providing guidance and supervision

Directive interview a highly structured interview that uses closed questions to elicit specific information

Dirty denotes the likely presence of microorganisms, some of which may be capable of causing infection

Disaccharides sugars that are composed of double molecules

Discharge planning the process of anticipating and planning for client needs after discharge

Discovery (legal) pretrial activities to gain all the facts of a situation

Discrimination the differential treatment of individuals or groups

Discussion an informal oral consideration of a subject by two or more healthcare personnel to identify a problem or establish strategies to resolve a problem

Disease an alteration in body function resulting in a reduction of capacities or shortening of the normal lifespan

Disengagement theory aging involves mutual withdrawal (disengagement) between an older individual and others in that individual's environment

Disinfectant agent that destroys microorganisms other than spores

Distance learning learning in which individuals communicate effectively across long distances

Distribution the transportation of a drug from its site of absorption to its site of action

Diuresis *see* Polyuria

Diuretics agents that increase urine secretion

Diversity the fact or state of being different

Documenting the process of making an entry on a client record; charting, recording

Do not resuscitate (DNR) order given by a primary care provider that is generally written when the client or proxy has expressed the wish for no resuscitation in the event of a respiratory or cardiac arrest

Dorothea Dix woman leader who provided nursing care during the Civil War

Dorsal position *see* Supine position

Dorsal recumbent (back-lying) position a supine position with the head and shoulders slightly elevated

Drop factor the number of drops that equal 1 mL as specified on the package of IV tubing

Droplet nuclei residue of evaporated droplets emitted by an infected host, such as someone with tuberculosis, that can remain in the air for long periods of time

Droplet precautions used for clients known or suspected to have serious illnesses transmitted by particle droplets larger than 5 microns (diphtheria, mycoplasma, pneumonia)

Drug a chemical compound taken for disease prevention, diagnosis, cure, or relief or to affect the structure or function of the body

Drug abuse excessive intake of a substance either continually or periodically

Drug allergy an immunologic reaction to a drug

Drug dependence inability to keep the intake of a drug or substance under control

Drug habituation a mild form of psychologic dependence on a drug

Drug half-life the time required for the elimination process to reduce the concentration of a drug to one-half of what it was at initial administration; also called *elimination half-life*

Drug interaction the beneficial or harmful interaction of one drug with another drug

Drug tolerance a condition in which successive increases in the dosage of a drug are required to maintain a given therapeutic effect

Drug toxicity the quality of a drug that exerts a deleterious effect on an organism or tissue

dry powder inhaler (DPI) An inhalation device for administering a solid drug to be released upon inhalation by the client

Dullness (of sound) a thudlike sound produced by dense tissue such as the liver, spleen, or heart

Durable medical equipment (DME) company a company that provides healthcare equipment for clients at home

Duration (of sound) its length (long or short) during auscultation

Duty (legal) the nurse must have (or should have had) a relationship with the client that involves providing care and following an acceptable standard of care

Dysesthesia an unpleasant abnormal sensation that mimics the pathology of central neuropathic pain disorder, such as pain that follows a stroke or spinal cord injury

Dysmenorrhea painful menstruation

Dyspareunia pain during or immediately after intercourse

Dysphagia difficulty swallowing

Dyspnea difficult or labored breathing

Dysrhythmia a pulse with an irregular rhythm

Dysuria painful or difficult voiding

Eastern medicine an approach to health that emphasizes prevention and natural healing

Eccrine glands glands that produce sweat; found over most of the body

Echocardiogram a noninvasive test that uses ultrasound to visualize structures of the heart and evaluate left ventricular function

Ecomap a visualization of how the family unit interacts with the external community environment, such as schools, religious commitments, occupational duties, and recreational pursuits

Ectoderm the outer layer of tissue formed in the second week of life

Edema the presence of excess interstitial fluid in the body that makes skin appear swollen, shiny, and taut, and tends to blanch color

Effectiveness a measure of the quality or quantity of services provided

Efficiency a measure of the resources used in the provision of nursing services

Effleurage a stroking massage technique

Ego the realistic part of the individual that balances the gratification demands of the id with the limitations of social and physical circumstances

Ego defense mechanisms unconscious psychologic adaptive mechanisms that work to protect the individual from anxiety

E-Health use of technology in the delivery of healthcare and health information

Ejaculation expulsion of seminal fluid and sperm

Elderspeak speech style similar to babytalk; gives the message of dependence and incompetence to older adults

Elective surgery performed when surgical intervention is the preferred treatment for a condition that is not imminently life threatening or to improve the client's life

Electric shock occurs when a current travels through the body to the ground rather than through electric wiring, or from static electricity that builds up on the body

Electrocardiogram (ECG, EKG) a graph of the electrical activity of the heart

Electrocardiography provides a graphic recording of the heart's electrical activity

Electroencephalogram (EEG) a graph of the electrical activity of the brain

Electrolytes chemical substances that develop an electric charge and are able to conduct an electric current when placed in water; ions

Electromyogram (EMG) a graph of the electrical activity of muscles

Electronic communication communication involving computers and technology (i.e., email)

Electronic health records (EHRs) *see* Computer-based patient records (CPRs)

Electro-oculogram (EOG) a graph of the electrical activity of eye-to-eye movement

Elimination half-life *see* Drug half-life

Email the most common form of electronic communication

Embolus a blood clot (or a substance such as air) that has moved from its place of origin and is causing obstruction to circulation elsewhere (plural: *emboli*)

Embryonic phase the phase during which the fertilized ovum develops into an organism with most of the features of a human

Emergency surgery surgery that is performed immediately to preserve function or the life of the client

Emmetropic normal refraction so that the eyes focus images on the retina

Emotional intelligence (EI) the ability to form work relationships with colleagues, display maturity in a variety of situations, and resolve conflicts while taking into consideration the emotions of others

Empathy the ability to discriminate what the other individual's world is like and to communicate to the other this understanding in a way that shows that the helper understands the client's feelings and the behavior and experience underlying these feelings

Emphysema a chronic pulmonary condition in which the alveoli are dilated and distended

Empirical knowing knowledge that comes from science; ranges from factual, observable phenomena to theoretical analysis

Encoding involves the selection of specific signs or symbols (codes) to transmit the message, such as which language and words to use, how to arrange the words, and what tone of voice and gestures to use

Endocardium a layer of the heart wall lining the inside of the heart's chambers and great vessels

Endoderm the inner layer of tissue formed in the second week of life

End-of-life care the care provided in the final weeks before death

Endogenous developing from within

Enema used most often as a treatment for constipation, it distends the intestine and sometimes irritates the intestinal mucosa, thereby increasing peristalsis and the excretion of feces and flatus

Energy the force that integrates the body, mind, and spirit

Enhanced Nurse Licensure Compact (ENLC) allows all RNs and LPNs to have one multistate license, with the ability to practice in both their home state and all other compact states

Enteral through the gastrointestinal system

Entoderm *see* Endoderm

Enuresis bedwetting; involuntary urination in children beyond the age when voluntary bladder control is normally acquired

Environment all of the conditions, circumstances, and influences surrounding and affecting the development of an organism or individual

Enzymes biological catalysts that speed up chemical reactions

Epicardium the visceral pericardium adhering to the surface of the heart, forming the heart's outermost layer

Epidural the injection of an anesthetic agent into the epidural or intrathecal (subarachnoid) space

Epidural anesthesia the injection of an anesthetic agent into the epidural space; also known as *peridural anesthesia*

Equianalgesia refers to the relative potency of various opioid analgesics compared to a standard dose of parenteral morphine

Equilibrium a state of balance

Ernest Grant first male president of the American Nurses Association

Erythema a redness tinge of skin color associated with a variety of skin rashes

Erythrocytes red blood cells (RBCs)

Eschar necrotic tissue

Essential amino acids amino acids that cannot be manufactured in the body and must be supplied as part of the protein ingested in the diet

Ethical knowing knowledge that focuses on matters of obligation or what ought to be done

Ethics the rules or principles that govern right conduct

Ethnicity a relationship among individuals who believe that they have distinctive characteristics that make them a group

Ethnocentrism the belief that one's own culture or way of life is better than that of others

Ethnography research that provides a framework to focus on the culture of a group of individuals

Ethnopharmacology study of the effect of ethnicity on responses to prescribed medicines

Etiology the causation of a disease or condition

Eupnea normal, quiet breathing

Eustachian tube the part of the middle ear that connects the middle ear to the nasopharynx; stabilizes air pressure between the external atmosphere and the middle ear

Euthanasia the act of painlessly putting to death individuals suffering from incurable or distressing disease

Evaluating a planned ongoing, purposeful activity in which clients and healthcare professionals compare expected outcomes with actual outcomes

Evaluation statement a statement that consists of two parts: a conclusion and supporting data

Evaporation continuous vaporization of moisture from the respiratory tract and from the mucosa of the mouth and from the skin

Evidence-based practice (EBP) the use of some form of substantiation in making clinical decisions

Evisceration extrusion of the internal organs

Exacerbation the period during a chronic illness when symptoms reappear after remission

Excitement phase part of the response cycle, involves vasocongestion and myotonia

Excoriation loss of the superficial layers of the skin

Excretion elimination of a waste product produced by the body cells from the body

Exhalation (expiration) breathing out, or the movement of gases from the lungs to the atmosphere

Exogenous developing from outside sources

Exophthalmos a protrusion of the eyeballs with elevation of the upper eyelids, resulting in a startled or staring expression

Expectorate spit out

Expert witness one who has special training, experience, or skill in a relevant area and is allowed by the court to offer an opinion on some issue within that area of expertise

Expiration (exhalation) the outflow of air from the lungs to the atmosphere

Express consent an oral or written agreement

Extended family family that includes the relatives of the nuclear family (e.g., grandparents, aunts, uncles)

External auditory meatus the entrance to the ear canal

Extinction the failure to perceive touch on one side of the body when two symmetric areas of the body are touched simultaneously

Extracellular fluid (ECF) fluid found outside the body cells

Extraneous variables any variables that could influence the results of the study other than the specific variable[s] being studied for their influence

Extravasation infiltration that involves a *vesicant*, a medication or fluid that causes blisters, severe tissue injury, or necrosis if it escapes from the vein

Exudate purulent drainage

Fabiola a wealthy Roman matron; viewed by some as the patron saint of early nursing who used her position and wealth to establish hospitals for the sick

Fad a widespread but short-lived interest, or a practice followed with considerable zeal

Failure to thrive (FTT) a unique syndrome in which an infant falls below the fifth percentile for weight and height on a standard growth chart or is falling in percentiles on a growth chart

Faith refers to our beliefs and expectations about life, ourselves, and others

False imprisonment the unlawful restraint or detention of another individual against his or her wishes

Family the basic unit of society that consists of those individuals, male or female, youth or adult, legally or not legally related, genetically or not genetically related, who are considered by others to represent their significant individuals

Family-centered nursing nursing that considers the health of the family as a unit in addition to the health of individual family members

Fasciculation an abnormal contraction of a bundle of muscle fibers that appears as a twitch

Fats lipids that are solid at room temperature

Fat-soluble vitamins A, D, E, and K vitamins that the body can store

Fatty acids the basic structural units of most lipids made up of carbon chains and hydrogen

Fear an emotion or feeling of apprehension aroused by impending or seeming danger, pain, or another perceived threat

Febrile pertaining to a fever; feverish

Fecal impaction a mass or collection of hardened, putty-like feces in the folds of the rectum

Fecal incontinence *see* Bowel incontinence

Feces excreted waste products; also called *stool*

Feedback the response or message that the receiver returns to the sender during communication; the mechanism by which some of the output of a system is returned to the system as input

Felony a crime of a serious nature, such as murder, punishable by a term in prison

Female orgasmic disorder when the female sexual response stops before orgasm occurs

Female sexual arousal disorder when lack of vaginal lubrication causes discomfort or pain during sexual activity

Fetal phase characterized by a period of rapid growth in the size of the fetus; both genetic and environmental factors affect its growth

Fever elevated body temperature

Fever spike a temperature that rises to fever level rapidly following a normal temperature and then returns to normal within a few hours

Fibrin an insoluble protein formed from fibrinogen during the clotting of blood

Fidelity a moral principle that obligates the individual to be faithful to agreements and responsibilities he or she has undertaken

Filtration process whereby fluid and solutes move together across a membrane from one compartment to another

Filtration pressure the pressure in a compartment that results in the movement of fluid and substances dissolved in fluid out of the compartment

First-level manager a manager responsible for managing the work of nonmanagerial personnel and the day-to-day activities of a specific work group or groups

Fissures deep grooves that occur as a result of dryness and cracking of the skin

Fixation immobilization or the inability of the personality to proceed to the next developmental stage because of anxiety

Flaccid weak or lax

Flatness (of sound) an extremely dull sound produced, during percussion, by very dense tissue, such as muscle or bone

Flatulence the presence of excessive amounts of gas in the stomach or intestines

Flatus gas or air normally present in the stomach or intestines

Florence Nightingale considered the founder of modern nursing, she was influential in developing nursing education, practice, and administration

Flow sheet a record of the progress of specific or specialized data such as vital signs, fluid balance, or routine medications; often charted in graph form

Fluid volume deficit (FVD) (hypovolemia) loss of both water and electrolytes in similar proportions from the extracellular fluid

Fluid volume excess (FVE) (hypervolemia) retention of both water and sodium in similar proportions to normal extracellular fluid (ECF)

Focus charting a method of charting that uses key words or foci to describe what is happening to the client

Focused interview an interview in which the nurse asks the client specific questions to collect information related to the client's problem

Folk medicine beliefs and practices relating to illness prevention and healing that derive from cultural traditions rather than from modern medicine's scientific base

Fontanels unossified membranous gaps in the bone structure of the skull of a newborn that make molding of the head possible

Food diary a detailed record of measured amounts (portion sizes) of all food and fluids a client consumes during a specified period, usually 3 to 7 days

Food frequency record a checklist that indicates how often general food groups or specific foods are eaten

Foot drop plantar flexion contracture

Foreseeability a link that must exist between the nurse's act and the injury suffered

Formal leader an appointed leader selected by an organization and given official authority to make decisions and act

Formal nursing care plan a written or computerized guide that organizes information about the client's care

Fowler's position a semisitting position in which the head and trunk are raised 45° and 60° relative to the bed (typically at 45°) and the knees may be bent or may not be flexed

Fremitus the faintly perceptible vibration felt through the chest wall when the client speaks (tactile fremitus)

Friction rubbing; the force that opposes motion

Functional strength ability of the body to perform work

Fungi infection-causing microorganisms that include yeasts and molds

Gait the way an individual walks

Gastrocolic reflex increased peristalsis of the colon after food has entered the stomach

Gastrostomy an opening through the abdominal wall into the stomach

Gastrostomy tube a tube that is surgically placed directly into the client's stomach and provides another route for administering nutrition and medications

Gauge the diameter of the shaft of a needle; the larger the gauge number, the smaller the diameter of the shaft

Gender expression the outward manifestation of an individual's sense of maleness or femaleness as well as what is perceived as gender-appropriate behavior

Gender identity an individual's self-image as a female or male

General adaptation syndrome (GAS) (Selye) a general arousal response of the body to a stressor characterized by certain physiologic events and dominated by the sympathetic nervous system

General anesthesia the induced loss of all sensation and consciousness

Generalizations statements about common cultural patterns that may not hold true at the individual level

Generation X generation that includes those born in years 1965–1978

Generation Y generation that includes those born in years 1979–2000

Generativity concern for establishing and guiding the next generation

Generic name (of drug) given before a drug officially becomes an approved medication; generally used throughout the drug's lifetime

Genital intercourse penile–vaginal intercourse (coitus)

Genogram composed of visual representations of gender and lines of birth descent through the generations

Geragogy the term used to describe the process involved in stimulating and helping older adults to learn

Geriatrics medical care of older adults

Gerontology the study of aging and older adults

Gingiva the gum

Gingivitis red, swollen gingivae (gums)

Glaucoma a disturbance in the circulation of aqueous fluid that causes an increase in intraocular pressure

Global self refers to the collective beliefs and images one holds about oneself; the most complete description that individuals can give of themselves at any one time

Global self-esteem how much one likes one's perceived self as a whole

Glossitis inflammation of the tongue

Glycerides the most common form of lipids consisting of a glycerol molecule with up to three fatty acids

Glycogen the chief carbohydrate stored in the body, particularly in the liver and muscles

Goals or desired outcomes a part of a care plan that describes, in terms of observable client responses, what the nurse hopes to achieve by implementing the nursing interventions

Governance the establishment and maintenance of social, political, and economic arrangements by which practitioners control their practice, self-discipline, working conditions, and professional affairs

Granulation tissue young connective tissue with new capillaries formed in the wound healing process

Grief emotional suffering often caused by bereavement

Gross negligence involves extreme lack of knowledge, skill, or decision making that the individual clearly should have known would put others at risk for harm

Grounded theory research to understand social structures and social processes; this method focuses on the generation of categories or hypotheses that explain patterns of behavior of individuals in the study

Growth physical change and increase in size

Guaiac test performed for occult (hidden) blood in the stool to detect gastrointestinal bleeding not visible to the eye

Guided imagery state of focused attention that encourages changes in attitudes, behavior, and physiologic reactions

Gustatory referring to the sense of taste

Habit training attempts to keep clients dry by having them void at regular intervals; also referred to as *timed voiding* or *scheduled toileting*

Hand-mediated biofield therapies using the hands to alter the biofield, or energy field

Handoff communication process in which information about client care is communicated

Harm (injury) the client or plaintiff must demonstrate some type of harm or injury (physical, financial, or emotional) as a result of the breach of duty owed the client; the plaintiff will be asked to document physical injury, medical costs, loss of wages, "pain and suffering," and any other damages

Harriet Tubman African American woman known as "the Moses of Her People" for her work with the Underground Railroad; during the Civil War she nursed the sick and suffering of her own race

Health degree of wellness or well-being that the client experiences

Health behaviors the actions an individual takes to understand his or her health state, maintain an optimal state of health, prevent illness and injury, and reach his or her maximum physical and mental potential

Health beliefs concepts about health that an individual believes are true

Healthcare-associated infections (HAIs) those that originate in any healthcare setting

Healthcare proxy a legal statement that appoints a proxy to make medical decisions for the client in the event the client is unable to do so

Healthcare system the totality of services offered by all health disciplines

Health disparities differences in care experienced by one population compared with another population

Health equity the highest possible standard of health for all individuals, especially those at greatest risk for poor health

Health informatics the management of healthcare information, using computers; also called *health information technology*

Health literacy ability to read, understand, and act on provided health information

Health maintenance organization (HMO) a group healthcare agency that provides basic and supplemental health maintenance and treatment services to voluntary enrollees

Health promotion a process to facilitate movement toward accomplishment of health goals by supporting individuals to make lifestyle changes and create an environment conducive to health

Health promotion diagnosis relates to clients' preparedness to implement behaviors to improve their health condition

Health risk assessment (HRA) an assessment and educational tool that indicates a client's risk for disease or injury during the next 10 years by comparing the client's risk with the mortality risk of the corresponding age, sex, and racial group

Health status the health of an individual at a given time

Heart failure a condition that develops if the heart cannot keep up with the body's need for oxygen and nutrients to the tissues; usually occurs because of myocardial infarction, but it may also result from chronic overwork of the heart

Heart-lung death the traditional clinical signs of death: cessation of the apical pulse, respirations, and blood pressure

Heat balance the state an individual is in when the amount of heat produced by the body exactly equals the amount of heat lost

Heat exhaustion condition that is the result of excessive heat and dehydration

Heat stroke life-threatening condition with body temperature greater than 41°C (106°F)

Heimlich maneuver abdominal thrusts used to clear an obstructed airway

Helix the posterior curve of the auricle's upper aspect

Helping relationships the nurse–client relationship

Hematocrit (Hct) the proportion of red blood cells (erythrocytes) to the total blood volume

Hematoma a contusion or "black eye" resulting from injury

Hemoglobin (Hgb) the red pigment in red blood cells that carries oxygen

Hemoglobin A1C (HbA1C) measurement of blood glucose that is bound to hemoglobin

Hemolytic transfusion reaction destruction of red blood cells as a result of transfusion of incompatible blood

Hemoptysis the presence of blood in the sputum

Hemorrhage excessive loss of blood from the vascular system

Hemorrhoids distended veins in the rectum

Hemostasis cessation of bleeding

Hemothorax the accumulation of blood in the pleural cavity

Herbal medicine treating illness with herbs

Heritage things passed down from previous generations

Heritage consistent identifying with one's traditional cultural heritage

Heritage inconsistent acculturated into the local culture in which one resides

Hernia a protrusion of an organ or tissue through an opening such as the abdominal or inguinal muscles

Higher brain death *see* Cerebral death

High-Fowler's position position in which the head and trunk are raised 60° to 90°, and most often the client is sitting upright at a right angle to the bed

Hirsutism the growth of excessive body hair

Holism combined mental, emotional, spiritual, relationship, and environmental components that are considered to play crucial and equal roles in an individual's state of health

Holistic health belief holds that the forces of nature must be maintained in balance or harmony

Holy days solemn religious observances and feast days throughout the year

Home healthcare healthcare professionals providing services in the home setting to clients recovering from an acute illness or injury or those with a disability or a chronic condition

Home health nursing care services and products provided to clients in their homes that are needed to maintain, restore, or promote their physical, psychologic, and social well-being

Homeopathy an alternative therapy based on the theory that the cure for the disease lies in the disease itself; thus, treatment is with highly diluted amounts of substances that at a higher concentration would produce the same symptoms as the disease

Homeostasis the tendency of the body to maintain a state of balance or equilibrium while continually changing; a mechanism in which deviations from normal are sensed and counteracted

Homocysteine an amino acid that has been shown to be increased in many individuals with atherosclerosis

Hordeolum redness, swelling, and tenderness of the hair follicle and glands that empty at the edge of the eyelids; also called a *sty*

Horticultural therapy adjunct therapy to occupational and physical therapy that may involve viewing nature, visiting a healing garden or wander garden, or actively gardening; also called *gardening* or *healing garden*

Hospice care that focuses on support and care for the dying individual and family, with the goal of facilitating a peaceful and dignified death

Hospice nursing focuses on caring and supportive nursing and medical interventions to promote a good death

Hospital information system (HIS) computer software program suite used to manage client, financial, and administrative data

Hub the part of the needle that fits onto the syringe

Humanist a perspective that includes propositions such as the mind and body are indivisible, people have the power to solve their own problems, and people are responsible for their lives and well-being

Humanistic learning theory focuses on both the cognitive and affective qualities of the learner

Humidifier a device that adds water vapor to inspired air

Humoral immunity antibody-mediated defense; resides ultimately in the B lymphocytes and is mediated by the antibodies produced by B cells

Hydrostatic pressure the pressure a liquid exerts on the sides of the container that holds it

Hygiene the science of health and its maintenance

Hypercalcemia an excess of calcium in the blood plasma

Hypercapnia a condition in which carbon dioxide accumulates in the blood

Hypercarbia (hypercapnia) accumulation of carbon dioxide in the blood

Hyperchloremia an excess of chloride in the blood plasma

Hyperinflation giving the client breaths that are greater than the client's normal tidal volume set on the ventilator through the ventilator circuit or via a manual resuscitation bag

Hyperkalemia an excess of potassium in the blood plasma

Hypermagnesemia an excess of magnesium in the blood plasma

Hypernatremia an excess of sodium in the blood plasma

Hyperopia farsightedness

Hyperoxygenation increasing the oxygen flow before suctioning and between suction attempts to avoid suction-related hypoxemia

Hyperphosphatemia an excess of phosphate in the blood plasma

Hyperpyrexia an extremely high body temperature (e.g., 41°C [105.8°F])

Hyperresonance an abnormal booming sound produced during percussion of the lungs

Hypersomnia condition where the affected individual obtains sufficient sleep at night but still cannot stay awake during the day

Hypertension an abnormally high blood pressure; over 140 mmHg systolic and/or 90 mmHg diastolic

Hyperthermia a body temperature above the usual range

Hypertonic solutions that have a higher osmolality than body fluids

Hypertrophy enlargement of a muscle or organ

Hyperventilation very deep, rapid respirations

Hypervolemia increased blood volume

Hypnotherapy application of hypnosis (trance state or altered state of consciousness) to a medical or psychologic disorder

Hypoactive sexual desire disorder a deficiency in or absence of sexual fantasies and persistently low interest or a total lack of interest in sexual activity

Hypocalcemia deficiency of calcium in the blood plasma

Hypochloremia deficiency of chloride in the blood plasma

Hypodermic under the skin

Hypodermic syringe a type of syringe that comes in 2-, 2.5-, and 3-mL sizes; the syringe usually has two scales marked on it: the minim and the milliliter

Hypokalemia deficiency of potassium in the blood plasma

Hypomagnesemia deficiency of magnesium in the blood plasma

Hyponatremia deficiency of sodium in the blood plasma

Hypophosphatemia deficiency of phosphate in the blood plasma

Hypotension an abnormally low blood pressure; less than 100 mmHg systolic in an adult

Hypothermia a core body temperature below the lower limit of normal

Hypothesis a prediction of the relationships among two or more variables

Hypotonic solutions that have a lower osmolality than body fluids

Hypoventilation very shallow respirations

Hypovolemia an abnormal reduction in blood volume

Hypoxemia low partial pressure of oxygen or low saturation of oxyhemoglobin in the arterial blood

Hypoxia insufficient oxygen anywhere in the body

Iatrogenic disease disease caused unintentionally by medical therapy

Iatrogenic infections infections that are the direct result of diagnostic or therapeutic procedures

Id the source of instinctive and unconscious psychologic urges

Ideal body weight (IBW) the optimal weight recommended for optimal health

Ideal self how we would prefer to be; the individual's perception of how one should behave based on certain personal standards, aspirations, goals, or values

Identification perceiving one's self as similar to and behaving like another individual

Idiosyncratic effect a different, unexpected, or individual effect from the normal one usually expected from a medication; the occurrence of unpredictable and unexplainable symptoms

iGeneration generation that includes those born in the years 1995–2012

Ileal conduit urinary diversion in which the client must wear an external pouch over the stoma to collect the continuous flow of urine; also known as *ileal loop*

Ileostomy a colostomy that generally empties from the distal end of the small intestine

Illicit drugs drugs that are sold illegally; street drugs

Illness a highly personal state in which an individual feels unhealthy or ill; may or may not be related to disease

Illness behavior the course of action an individual takes to define the state of his or her health and pursue a remedy

Imagery a two-way communication between the conscious and unconscious mind involving the whole body and all its senses

Imagination an important part of preschoolers' life (the preschooler has an active imagination and fantasizes in play)

Imitation copying the behaviors and attitudes of another individual

Immobility prescribed or unavoidable restriction of movement in any area of an individual's life

Immune defenses *see* Specific defenses

Immunity a specific resistance of the body to infection; it may be natural, or resistance may develop after exposure to a disease agent

Immunoglobulins *see* Antibodies

Implementing the phase of the nursing process in which the nursing care plan is put into action

Implied consent consent that is assumed in an emergency when consent cannot be obtained from the client or a relative

Implied contract a contract that has not been explicitly agreed to by the parties but that the law nevertheless considers to exist

Incentive spirometer a device that measures the flow of air inhaled through a mouthpiece; also called a *sustained maximal inspiration device (SMI)*

Incivility behaviors that are disrespectful, rude, and impolite, and promote conflict while increasing stress

Incomplete proteins proteins that lack one or more essential amino acids; usually derived from vegetables

Incus the anvil bone of the middle ear

Independent functions areas of healthcare unique to nursing, separate and distinct from medical management

Independent interventions activities that the nurse is licensed to initiate as a result of the nurse's own knowledge and skills

Independent practice associations (IPAs) provide care in offices; clients pay a fixed prospective payment and the IPA pays the provider; earnings or losses are assumed by the IPA

Independent variable the presumed cause or influence on a dependent variable

Indicator an observable client state, behavior, or self-reported perception or evaluation; similar to desired outcomes in traditional language

Individualized care plan a plan tailored to meet the unique needs of a specific client—needs that are not addressed by the standardized plan

Inductive reasoning making generalizations from specific data

Infection the disease process produced by microorganisms

Inferences interpretations or conclusions made based on cues or observed data

Inferential statistics allows researchers to test hypotheses about relationships between variables or differences between groups

Infiltration occurs when the tip of an IV is outside the vein and the fluid is entering the tissues instead; manifested by local swelling, coolness, pallor, and discomfort at the IV site

Inflammation local and nonspecific defensive tissue response to injury or destruction of cells

Influence an informal strategy used to gain the cooperation of others without exercising formal authority

Inflicted traumatic brain injury *see* Abusive head trauma

Informal leader an individual selected by a group as its leader because of seniority, age, special abilities, or charisma

Informal nursing care plan a strategy for action that exists in the nurse's mind

Informatics the science of computer information systems

Information technology (IT) use of computers to systematically solve problems

Informed consent a client's agreement to accept a course of treatment or a procedure after receiving complete information, including the risks of treatment and facts relating to it, from the healthcare provider

Ingrown toenail the growing inward of a nail into the soft tissues around it; most often results from improper nail trimming

Inhalation the intake of air into the lungs; also called *inspiration*

Inhibiting effect the decreased effect of one or both drugs

Injury *see* Harm

Input consists of information, material, or energy that enters a system

Inquest a legal inquiry into the cause or manner of a death

Insensible fluid loss fluid loss that is not perceptible to an individual

Insensible heat loss heat loss that occurs from evaporation (vaporization) of moisture from the respiratory tract, mucosa of the mouth, and the skin

Insensible water loss continuous and unnoticed water loss

In-service education education that is designed to upgrade the knowledge or skills of employees

Insomnia inability to fall asleep or remain asleep

Inspection visual examination, which is assessing by using the sense of sight

Inspiration *see* Inhalation

Insulin syringe syringe that has a scale specially designed for insulin and is the only type of syringe that should be used to administer insulin

Integrated delivery system (IDS) a system that incorporates acute care services, home healthcare, extended and skilled care facilities, and outpatient services

Integrated healthcare system one that makes all levels of care available in an integrated form—primary care, secondary care, and tertiary care

Integrative medicine combines treatments from conventional medicine and complementary and alternative medicine for which there is high-quality evidence of safety and effectiveness

Intensity the loudness or softness of auscultated sound

Intention tremor involuntary trembling when an individual attempts a voluntary movement

Intermittent fever a body temperature that alternates at regular intervals between periods of fever and periods of normal or subnormal temperatures

Internet a worldwide computer network

Interpersonal skills all verbal and nonverbal activities individuals use when communicating directly with one another

Interpreter an individual who mediates spoken communication between individuals speaking different languages without adding, omitting, or distorting meaning or editorializing

Intersex a condition in which there are contradictions among chromosomal sex, gonadal sex, internal organs, and external genital appearance that result in ambiguous gender

Interstitial fluid fluid that surrounds the cells; includes lymph

Interview a planned communication; a conversation with a purpose

Intimacy a close friendship

Intracellular fluid (ICF) fluid found within the body cells; also called *cellular fluid*

Intradermal under the epidermis (into the dermis)

Intradermal (ID) injection the administration of a drug into the dermal layer of the skin just beneath the epidermis

Intramuscular into the muscle

Intramuscular (IM) injection the administration of a drug into the muscle tissue

Intraoperative phase the phase of surgery that begins when the client is transferred to the operating room and ends when the client is admitted to the postanesthesia care unit (PACU), also called the postanesthesia room (PAR)

Intraspinal (intrathecal) into the spinal canal

Intrathecal *see* Intraspinal

Intravascular fluid plasma

Intravenous within a vein

Intravenous pyelography (IVP) x-ray filming of the kidney and ureters after injection of a radiopaque material into the vein

Introjection the assimilation of the attributes of others

Intuition the understanding or learning of things without the conscious use of reasoning

Invasion of privacy a direct wrong of a personal nature, it injures the feelings of the individual and does not take into account the effect of revealed information on the standing of the individual in the community

Ions atoms or group of atoms that carry a positive or negative electric charge; electrolytes

Iron deficiency anemia a form of anemia caused by inadequate supply of iron for synthesis of hemoglobin

Irrigation a flushing or washing out with a specified solution; administration of a solution to wash out the conjunctival sac to remove

secretions or foreign bodies or to remove chemicals that may injure the eye

Ischemia deficiency of blood supply caused by obstruction of circulation to the body part

Isokinetic (resistive) exercises muscle contraction or tension against resistance

Isolation practices that prevent the spread of infection and communicable diseases

Isometric (static or setting) exercise muscle contraction without moving the joint (muscle length does not change), which involves exerting pressure against a solid object

Isotonic solutions that have the same osmolality as body fluids

Isotonic (dynamic) exercise exercise in which muscle tension is constant and the muscle shortens to produce muscle contraction and active movement

Jaundice a yellowish tinge to skin color

Jejunostomy a tube that is placed surgically or by laparoscopy through the abdominal wall into the jejunum for long-term nutritional support

Justice fairness

Kardex the trade name for a method that makes use of a series of cards to concisely organize and record client data and instructions for daily nursing care—especially care that changes frequently and must be kept up to date

Keloid a hypertrophic scar containing an abnormal amount of collagen

Kidneys, ureters, and bladder (KUB) x-ray of the kidneys, ureters, and bladder

Kilojoule (kJ) a metric measurement referring to the amount of energy required when a force of 1 newton (N) moves 1 kg of weight 1 m of distance

Kinesthetic refers to awareness of the position and movement of body parts

Knights of Saint Lazarus an order of knights that dedicated themselves to the care of individuals with leprosy, syphilis, and chronic skin conditions

Korotkoff sounds the five phases of blood pressure sounds

Kyphosis excessive convex curvature of the thoracic spine

Laissez-faire (permissive) leader recognizes a group's need for autonomy and self-regulation

Lanugo the fine hair on the body of the fetus, also referred to as down or woolly hair

Large calorie (Calorie, kilocalorie [Kcal]) the amount of heat energy required to raise the temperature of 1 gram of water 15ºC to 16ºC; the unit used in nutrition

Lateral (side-lying) position position in which an individual lies on one side of the body

Lavage an irrigation or washing of a body organ, such as the stomach

Lavinia L. Dock a nursing leader and suffragist who was active in the protest movement for women's rights that resulted in the U.S. Constitution amendment allowing women to vote in 1920

Law a rule made by humans that regulates social conduct in a formally prescribed and binding manner

Laxatives medications that stimulate bowel activity and assist fecal elimination

Leader an individual who influences others to work together to accomplish a specific goal

Leadership style describes traits, behaviors, motivations, and choices used by individuals to effectively influence others

Leading question a question that influences the client to give a particular answer

Learning a change in human disposition or capability that persists over a period of time and cannot be solely accounted for by growth

Learning need a desire or a requirement to know something that is currently unknown to the learner

Leukocytes white blood cells

Leukocytosis an increase in the number of white blood cells

Liability the quality or state of being legally responsible for one's obligations and action and to make financial restitution for wrongful acts

Libel defamation by means of print, writing, or pictures

Libido urge or desire for sexual activity

License a legal permit granted to individuals to engage in the practice of a profession and to use a particular title

Licensed practical nurse (LPN) provides direct client care under the direction of an RN, physician, or other licensed practitioner

Licensed vocational (practical) nurse (LVN/LPN) a nurse who practices under the supervision of a registered nurse, providing basic direct technical care to clients

Lifestyle the values and behaviors adopted by an individual in daily life

Lift an abnormal anterior movement of the chest related to enlargement of the right ventricle

Lillian Wald founder of the Henry Street Settlement and Visiting Nurse Service, which provided nursing and social services and organized educational and cultural activities; considered the founder of public health nursing

Linda Richards America's first formally trained nurse

Line of gravity an imaginary vertical line drawn through an object's center of gravity

Lipids organic substances that are greasy and insoluble in water but soluble in alcohol or ether

Lipoproteins soluble compounds made up of various lipids

Litigation the action of a lawsuit

Living will a document that states medical treatments(s) the client chooses to omit or refuse in the event that the client is unable to make these decisions

Livor mortis discoloration of the skin caused by breakdown of the red blood cells, which occurs after blood circulation has ceased and appears in the lowermost or dependent areas of the body

Lobule earlobe

Local adaptation syndrome (LAS) the reaction of one organ or body part to stress

Local anesthesia an anesthetic agent used for minor surgical procedures that is injected into a specific area

Local infection an infection that is limited to the specific part of the body where the microorganisms remain

Locus of control (LOC) a concept about whether clients believe their health status is under their own or others' control

Logical positivism maintains that "truth" is absolute and can be discovered by careful measurement

Logrolling a technique used to turn a client whose body must at all times be kept in straight alignment

Long-term memory the repository for information stored for periods longer than 72 hours and usually weeks and years

Lordosis an exaggerated concavity in the lumbar region of the vertebral column

Loss an actual or potential situation in which something that is valued is changed or no longer available

Lumbar puncture procedure in which cerebrospinal fluid is withdrawn through a needle inserted into the subarachnoid space of the spinal canal between the third and fourth lumbar vertebrae, or between the fourth and fifth lumbar vertebrae; also called a *spinal tap*

Lung compliance expansibility of the lung

Lung recoil the tendency of lungs to collapse away from the chest wall

Lung scan records the emissions from radioisotopes that indicate how well gas and blood are traveling through the lungs; also known as a *V/Q* (ventilation/perfusion) *scan*

Luther Christman one of the founders of the American Assembly for Men in Nursing and the first male dean

Maceration the wasting away or softening of a solid as if by the action of soaking; often used to describe degenerative changes and eventual disintegration

Macrominerals any of the minerals that individuals require daily in amounts over 100 mg

Macronutrients carbohydrates, fats, and protein that are needed in large amounts to provide energy

Magico-religious health belief a belief system in which individuals attribute the fate of the world and those in it to the actions of God, the gods, or other supernatural forces for good or evil

Magnetic resonance imaging (MRI) a noninvasive diagnostic scanning technique in which the client is placed in a magnetic field

Maintenance stage stage at which an individual integrates newly adopted behavior patterns into his or her lifestyle

Major surgery surgery that involves a high degree of risk for a variety of reasons; it may be complicated or prolonged; large losses of blood may occur; vital organs may be involved; postoperative complications may occur

Male erectile disorder when a man has erection problems during 25% or more of his sexual interactions

Male orgasmic disorder disorder where a man can maintain an erection but has difficulty ejaculating

Malleus hammer bone of the middle ear

Malnutrition the lack of necessary or appropriate food substances that includes both undernutrition and overnutrition

Malpractice the negligent acts of individuals engaged in professions or occupations in which highly technical or professional skills are employed

Managed care a method of organizing care delivery that emphasizes communication and coordination of care among all healthcare team members

Management information system (MIS) software designed to facilitate the organization and application of data used to manage an organization or department

Manager one who is appointed to a position in an organization that gives the power to guide and direct the work of others

Mandated reporters a role of the nurse in which he or she identifies and assesses cases of violence against others, and in every case the situation must be reported to the proper authorities

Manometer a glass or plastic tube calibrated in millimeters that is used to take cerebrospinal pressure readings

Manslaughter second-degree murder

Manubrium the handle-like superior part of the sternum that joins with the clavicles

Margaret Higgins Sanger considered the founder of Planned Parenthood, was imprisoned for opening the first birth control information clinic in Baltimore in 1916

Mary Breckinridge a nurse who practiced midwifery in England, Australia, and New Zealand; founded the Frontier Nursing Service in Kentucky in 1925 to provide family-centered primary healthcare to rural populations

Mary Mahoney first African American professional nurse

Massage therapy the scientific manipulation of the soft tissues of the body

Mastoid a bony prominence behind the ear

Masturbation sexual self-stimulation

Maturation theory that children achieve milestone abilities and skills, such as rolling over, sitting, and walking at specific times, based on an in-born timetable

Maturity the state of maximal function and integration; the state of being fully developed

Mean arterial pressure (MAP) represents the pulse pressure actually delivered to the body's organs

Measures of central tendency measures that describe the center of a distribution of data, denoting where most of the participants lie; include the mean, median, and mode

Measures of variability measures that indicate the degree of dispersion or spread of the data; include range, variance, and standard deviation

Meatus referring to the urinary meatus, which is the external opening from the urethra to the surface of the body

Meconium the first fecal material passed by a newborn, normally up to 24 hours after birth

Medicaid a U.S. federal public assistance program paid out of general taxes and administered through the individual states to provide healthcare for those who require financial assistance

Medical asepsis all practices intended to confine a specific microorganism to a specific area, limiting the number, growth, and spread of microorganisms

Medical examiner a physician who usually has advanced education in pathology or forensic medicine who determines causes of death

Medicare a national and state health insurance program for U.S. residents older than 65 years of age

Medication a substance administered for the diagnosis, cure, treatment, or relief of a symptom or for prevention of disease

Medication reconciliation process of identifying the most accurate list possible of all medications a client is taking—including drug name, dosage, frequency, and route—and using this list to provide correct medications for clients anywhere within the healthcare system

Meditation various mindfulness techniques with key elements that include focused attention on the present moment or the body's experience; awareness, depth, and steadiness of breathing; and avoiding judgmental and intrusive thoughts

Menarche onset of menstruation

Meniscus the crescent-shaped upper surface of a column of liquid

Menopause cessation of menstruation

Menstruation the monthly discharge of blood through the vagina occurring in nonpregnant women from puberty to menopause

Mentor an individual who serves as an experienced guide, adviser, or advocate and assumes responsibility for promoting the growth and professional advancement of a less experienced individual

Mesoderm middle layer of the embryonic tissue that forms during the first 3 weeks of life

Metabolic acidosis a condition characterized by a deficiency of bicarbonate ions in the body in relation to the amount of carbonic acid in the body; the pH falls to less than 7.35

Metabolic alkalosis a condition characterized by an excess of bicarbonate ions in the body in relation to the amount of carbonic acid in the body; the pH rises to greater than 7.45

Metabolic syndrome (Met-S) a cluster of cardiovascular risk factors that increase the risk for cardiovascular disease, diabetes, and death

Metabolism the sum of all physical and chemical processes by which a living substance is formed and maintained and by which energy is made available for use by the organism; also called *biotransformation*

Metabolites end products or enzymes

Metacognitive processes include reflective thinking and awareness of the skills learned by the nurse in caring for the client. The nurse reflects on the client's status, and through the use of critical thinking skills determines the most effective plan of care.

Metaparadigm originates from the Greek *meta*, meaning "with," and *paradigm*, meaning "pattern"; based on four theoretical concepts of nursing: individual or client, environment, health, and nursing

Metered-dose inhaler (MDI) a handheld nebulizer that is a pressurized container of medication used by the client to release the medication through a mouthpiece

Methodology elements of the research process that deal with how the study is organized, who or what will be the sources of information for

the study, and data collection details such as what and how data will be collected and the timing of data collection

Microminerals a vitamin or mineral

Micronutrients those vitamins and minerals required in small amounts to metabolize the energy-providing nutrients

Micturition *see* Urination

Mid-arm circumference (MAC) a measure of fat, muscle, and skeleton

Mid-arm muscle area (MAMA) calculated by using reference tables or by using a formula that incorporates the triceps skinfold and the MAC

Middle-level manager a manager who supervises a number of first-level managers and is responsible for the activities in the departments supervised

Midstream urine specimen *see* Clean-catch specimen

Mild pain pain in the 1 to 3 range on a numeric scale of 0 (no pain) to 10 (worst pain imaginable)

Milliequivalent one-thousandth of an equivalent, which is the chemical combining power of a substance

Minerals a substance found in organic compounds, as inorganic compounds and as free ions

Minor surgery surgery that involves little risk, produces few complications, and is often performed in a "day surgery" facility

Miosis constricted pupils

Misdemeanor a legal offense usually punishable by a fine or a short-term jail sentence, or both

Mixed hearing loss a combination of conduction and sensorineural loss

Mobility ability to move about freely, easily, and purposefully in the environment

Modeling observing the behavior of individuals who have successfully achieved a goal that one has set for oneself and, through observing, acquiring ideas for behavior and coping strategies

Moderate pain pain in the 4 to 6 range on a numeric scale of 0 (no pain) to 10 (worst pain imaginable)

Monosaccharides sugars that are composed of single molecules

Monounsaturated fatty acids a fatty acid with one double bond

Moral relating to right and wrong

Moral behavior the way an individual perceives the requirements necessary for individuals to live together and how he or she responds to them

Moral development process of learning to tell the difference between right and wrong and of learning what ought and ought not to be done

Moral distress when what is in the client's best interest may be contrary to the nurse's personal belief system

Morality a doctrine or system denoting what is right and wrong in conduct, character, or attitude

Moral rules specific prescriptions for actions

Mortician an individual trained in care of the dead; also called an *undertaker*

Motivation the desire to learn

Mourning the process through which grief is eventually resolved or altered

Mucus clearance device (MCD) a small, handheld device that loosens mucus from the airways and assists its movement up the airways to be expectorated; used for clients with excessive secretions such as with cystic fibrosis, COPD, and bronchiectasis

Multicultural describes an individual who has multiple patterns of identification or crosses several cultures, lifestyles, and sets of values

Multidisciplinary care plan a standardized plan that outlines the care required for clients with common, predictable—usually medical—conditions

Multimodal pain management incorporates both pharmacologic and nonpharmacologic approaches to achieve the best possible outcomes for the client

Music therapy the behavioral science concerned with the systematic application of music to produce relaxation and desired changes in emotions, behavior, and physiology

Mutual pretense a type of awareness in which the client, family, and health personnel know that the prognosis is terminal but do not talk about it and make an effort not to raise the subject

Mutual recognition model a regulatory model developed by the National Council of State Boards of Nursing, which allows for multistate licensure

Mydriasis enlarged pupils

Myocardial infarction (MI) heart attack; cardiac tissue necrosis owing to obstruction of blood flow to the heart

Myocardium a layer of the heart wall; cardiac muscle cells that form the bulk of the heart and contract with each beat

Myopia nearsightedness

Narcolepsy an uncontrollable desire for sleep or attacks of sleep during the day

Narrative charting a descriptive record of client data and nursing interventions, written in sentences and paragraphs

Nasoenteric (nasointestinal) tube a tube inserted through one of the nostrils, down the nasopharynx, and into the alimentary tract

Nasogastric tube a tube inserted by way of the nasopharynx or the oropharynx; it is placed into the stomach for the temporary purpose of feeding the client or to remove gastric secretions

Nationality refers to the sovereign state or country where an individual has membership, which may be through birth, through inheritance (parents), or through naturalization

Naturalism maintains that reality is relative or contextual and constructed by individuals who are experiencing a phenomenon; sometimes referred to as *constructivism*

Naturopathic medicine practice that focuses on nutrition, herbs, physical therapy, spinal manipulation, acupuncture, lifestyle counseling, stress management, exercise therapy, homeopathy, and hydrotherapy

Nebulizer small machine that vaporizes a liquid medication into a fine mist that is inhaled, using a face mask or handheld device

Negative feedback feedback that inhibits change

Negligence failure to behave in a reasonable and prudent manner; an unintentional tort

Nephrostomy diversion of urine from a kidney to a stoma

Nerve block chemical interruption of a nerve pathway effected by injecting a local anesthetic

Networking a process by which individuals develop linkages throughout a profession to communicate, share ideas and information, and offer support and direction to each other

Neurogenic bladder interference with the normal mechanisms of urine elimination in which the client does not perceive bladder fullness and is unable to control the urinary sphincters; the result of impaired neurologic function

Neuropathic pain experienced by individuals who have damaged or malfunctioning nerves as a result of illness, injury, or undetermined reasons

Neutral question a question that does not direct or pressure a client to answer in a certain way

Nitrogen balance a measure of the degree of protein anabolism and catabolism; net result of intake and loss of nitrogen

Nociception the physiologic processes related to pain perception

Nociceptive pain experienced when an intact, properly functioning nervous system sends signals that tissues are damaged, requiring attention and proper care

Nociceptor a pain receptor

Nocturia voiding two or more times at night

Nocturnal emissions orgasm and emission of semen during sleep

Nocturnal enuresis involuntary urination at night

Nondirective interview an interview using open-ended questions and empathetic responses to build rapport and learn client concerns

Nonessential amino acids an amino acid that the body can manufacture

Noninvasive positive pressure ventilation (NPPV) delivery of air or oxygen under pressure without the need for an invasive tube such as an endotracheal tube or tracheostomy tube for clients who require mechanical assistance to maintain adequate breathing

Nonmaleficence the duty to do no harm

Nonspecific defenses bodily defenses that protect an individual against all microorganisms, regardless of prior exposure

Nonsteroidal anti-inflammatory drugs (NSAIDs) drugs such as aspirin and ibuprofen that have anti-inflammatory, analgesic, and antipyretic effects

Nonverbal communication communication other than words, including gestures, posture, and facial expressions

Norm an ideal or fixed standard; an expected standard of behavior of group members

Normocephalic normal head size

Normocephaly normal head circumference at birth; usually 35 cm (14 in.)

Nosocomial infections infections that originate in the hospital

NPO nothing by mouth; literally, "nil per os"

NREM (non-REM) sleep sleep during which the individual experiences non–rapid eye movement

Nuclear family a family of parents and their offspring

Nurse informaticist an expert who combines computer, information, and nursing science to develop policies and procedures that promote effective use of computerized records by nurses and other healthcare professionals

Nurse Licensure Compact (NLC) an agreement between two or more states that is the mechanism used to create mutual recognition among states

Nursing the attributes, characteristics, and actions of a nurse providing care on behalf of, or in conjunction with, a client

Nursing diagnosis the nurse's clinical judgment about individual, family, or community responses to actual and potential health problems and life processes to provide the basis for selecting nursing interventions to achieve outcomes for which the nurse is accountable

Nursing ethics ethical issues that occur in nursing practice

Nursing informatics the science of using computer information systems in the practice of nursing

Nursing intervention any treatment, based on clinical judgment and knowledge, that a nurse performs to enhance client outcomes

Nursing Interventions Classification (NIC) a taxonomy of nursing actions, each of which includes a label, a definition, and a list of activities

Nursing Outcomes Classification (NOC) a taxonomy for describing client outcomes that respond to nursing interventions

Nursing process a systematic, rational method of planning and providing nursing care

Nutrients organic, inorganic, energy-producing substances found in foods and required for body functioning

Nutrition the sum of all interactions between an organism and the food it consumes

Nutritive value the nutrient content of a specified amount of food

Nystagmus rapid involuntary rhythmic eye movement

Obese when body mass index (BMI) is greater than 30 kg/m^2

Objective data information (data) that is detectable by an observer or can be tested against an accepted standard; can be seen, heard, felt, or smelled; also called *signs*

Obligatory losses essential fluid losses required to maintain body functioning

Occult blood hidden blood

Occupational exposure skin, eye, mucous membrane, or parenteral contact with blood or other potentially infectious materials that may result from the performance of an employee's duties

Official name (of drug) the name under which a drug is listed in one of the official publications (e.g., the *United States Pharmacopeia*)

Oils lipids that are liquid at room temperature

Olfactory related to smell

Oliguria production of abnormally small amounts of urine by the kidney

Oncotic pressure *see* Colloid osmotic pressure

One-point discrimination the ability to sense whether one or two areas of the skin are being stimulated by pressure

Onset of action the time after drug administration when the body initially responds to the drug

Open awareness a type of awareness in which a client and individuals around know about an impending death

Open-ended questions questions that specify only a broad topic to be discussed and invite clients to discover and explore their thoughts and feelings about the topic

Open system system in which energy, matter, and information move into and out of the system through the system's boundary

Ophthalmic pertaining to medications for the eye

Opportunistic pathogen a microorganism causing disease only in a susceptible individual

Oral a method of administration in which the drug is swallowed

Oral–genital sex oral stimulation of either female or male genitals

Organizing determining responsibilities, communicating expectations, and establishing the chain of command for authority and communication

Orgasmic phase part of the response cycle, the involuntary climax of sexual tension, accompanied by physiologic and psychologic release

Orthopnea ability to breathe only when in an upright position (sitting or standing)

Orthopneic position a sitting position to relieve respiratory difficulty in which the client sits either in bed or on the side of the bed, leaning over an overbed table across the lap

Orthostatic hypotension decrease in blood pressure related to positional or postural changes from lying to sitting or standing positions

Osmolality the concentration of solutes in body fluids

Osmosis passage of a solvent through a semipermeable membrane from an area of lesser solute concentration to one of greater solute concentration

Osmotic pressure pressure exerted by the number of nondiffusible particles in a solution; the amount of pressure needed to stop the flow of water across a membrane

Ossicles the three middle ear bones of sound transmission

Osteoporosis demineralization of the bone

Ostomy an opening on the abdominal wall for the elimination of feces or urine

Otic refers to instillations or irrigations of the external auditory canal

Otoscope an instrument used to view the ear

Outcome evaluation focuses on demonstrable changes in a client's health status as a result of nursing care

Output energy, matter, or information from a system given out by the system as a result of its processes

Overhydration occurs when water is gained in excess of electrolytes, resulting in low serum osmolality and low serum sodium levels, also known as *hypo-osmolar imbalance* or *water intoxication*

Overnutrition refers to a caloric intake in excess of daily energy requirements, resulting in storage of energy in the form of increased adipose tissue

Overweight a BMI of 25 to 29.9 kg/m^2

Oxygen saturation (SpO_2) the percentage of all hemoglobin binding sites that are occupied by oxygen

Oxyhemoglobin the compound of oxygen and hemoglobin

Pace number of steps taken per minute or the distance taken in one step when walking

Packing filling an open wound or cavity with a material such as gauze

Pain whatever the experiencing individual says it is, existing whenever he or she says it does

Pain management alleviation of pain or a reduction in pain to a level of comfort that is acceptable to the client

Pain threshold the least amount of stimuli that is needed for an individual to label a sensation as pain

Pain tolerance the maximum amount of painful stimuli that an individual is willing to withstand without seeking avoidance of the pain or relief

Palliative care the prevention and relief of suffering by means of early identification and impeccable assessment and treatment of pain and other problems, physical, psychosocial, and spiritual

Pallor paleness

Palpation the examination of the body using the sense of touch

Papanicolaou (Pap) test a method of taking a sample of cervical cells for microscopic examination to detect malignancy

Parasites microorganisms that live in or on another organism from which they obtain nourishment

Parasomnia a cluster or pattern of waking behavior that appears during sleep, such as somnambulism (sleepwalking), sleeptalking, and enuresis (bedwetting)

Parenteral drug administration using a medication route other than the alimentary or digestive tract; injected into the body intradermally, subcutaneously, intramuscularly, or intravenously

Paresis slight or incomplete paralysis

Parotitis inflammation of the parotid salivary gland

Passive (acquired) immunity a resistance of the body to infection in which the host receives natural or artificial antibodies produced by another source

Passive euthanasia allowing an individual to die by withholding or withdrawing measures to maintain life

Passive ROM exercises range-of-motion exercises in which another individual moves each of the client's joints through their complete range of movement, maximally stretching all muscle groups within each plane over each joint

Pathogenicity the ability to produce disease; a pathogen is a microorganism that causes disease

Pathologic fractures spontaneous fractures to which older adults are prone

Patient an individual who is waiting for or undergoing medical treatment and care

Patient-controlled analgesia (PCA) an interactive method of pain management that permits clients to treat their pain by self-administering doses of analgesics

Patient Self-Determination Act (PSDA) legislation requiring that every competent adult be informed in writing on admission to a healthcare institution about his or her rights to accept or refuse medical care and to use advance directives

Peak level indicates the highest concentration of the drug in the blood serum

Peak plasma level the concentration of a drug in the blood plasma that occurs when the elimination rate equals the rate of absorption

Pedagogy the discipline concerned with helping children learn

Pediculosis (lice) infestation with head lice, *Pediculus capitis*; body lice, *Pediculus corporis*; or crab lice, *Pediculus pubis*

Peer groups assume great importance and have a number of functions: provide a sense of belonging, pride, social learning, and sexual roles; most peer groups have well-defined, gender-specific modes of acceptable behavior and in adolescence, the peer groups change with age

Penrose drain a flat, thin rubber tube inserted into a wound to allow for fluid to flow from the wound; it has an open end that drains onto a dressing

Perceived loss the loss experienced by an individual that cannot be verified by others

Perception the ability to interpret the environment through the senses

Percussion (in assessment) a method in which the body surface is struck to elicit sounds that can be heard or vibrations that can be felt

Percutaneous route of absorption of a topical medication through the skin

Percutaneous endoscopic gastrostomy (PEG) a procedure in which a PEG catheter is inserted into the stomach through the skin and subcutaneous tissues of the abdomen; used as a feeding tube

Percutaneous endoscopic jejunostomy (PEJ) a procedure in which a PEJ catheter is inserted into the jejunum through the skin and subcutaneous tissues of the abdomen; used as a feeding tube

Perfusion passage of blood constituents through the vessels of the circulatory system

Pericardium double layer of fibroserous membrane of the heart; the parietal, or outermost, pericardium serves to protect the heart and anchor it to surrounding structures

Peridural anesthesia *see* Epidural anesthesia

Periodontal disease disorder of the supporting structures of the teeth

Perioperative period refers to the three phases of surgery: preoperative, intraoperative, and postoperative

Peripheral pulse a pulse located in the periphery of the body (e.g., foot, hand, or neck)

Peripherally inserted central venous catheter (PICC) a long venous catheter inserted in an arm vein and extending into the distal third of the superior vena cava

Peripheral vascular resistance (PVR) impedance or opposition to blood flow to the tissues; determined by viscosity, or thickness, of the blood; blood vessel length; blood vessel diameter

Peristalsis wavelike movements produced by circular and longitudinal muscle fibers of the intestinal walls; the movement propels the intestinal contents onward

Permissive leader *see* Laissez-faire leader

PERRLA abbreviation used to record normal assessment of the pupils (*pupils equally round* and *react* to *light* and *accommodation*)

Persistent vegetative state (PVS) loss of cognitive function and awareness but respiration and circulation remain

Personality the outward expression of the inner self

Personal knowing promotes wholeness and integrity in the personal encounter to achieve engagement

Personal protective equipment (PPE) barriers such as gloves, mask, and gown used to protect individuals from contact with potentially infective materials

Personal space the distance individuals prefer in interactions with others

Personal values values internalized from the society or culture in which one lives

PES format the three essential components of nursing diagnostic statements including the terms describing the *problem*, the *etiology* of the problem, and the defining characteristics or cluster of *signs* and *symptoms*

pH a measure of the relative alkalinity or acidity of a solution; a measure of the concentration of hydrogen ions

Phagocytosis the process by which macrophages engulf microorganisms and cellular debris

Pharmacist an individual licensed to prepare and dispense drugs and prescriptions

Pharmacodynamics the mechanism of drug action and the relationships between drug concentration and resulting effects in the body

Pharmacogenetics the study of how DNA variation in a *single or few* genes influences the response to a single drug

Pharmacogenomics the study of how genes affect an individual's response to drugs

Pharmacokinetics the study of the absorption, distribution, biotransformation, and excretion of drugs

Pharmacology the scientific study of the actions of drugs on living animals and humans

Pharmacopoeia a book containing a list of drug products used in medicine, including their descriptions and formulas

Pharmacy the art of preparing, compounding, and dispensing drugs; also refers to the place where drugs are prepared and dispensed

Phenomenology research that investigates individuals' life experiences and how they interpret those experiences

Phlebotomist an individual from a laboratory who performs venipuncture, collecting the blood specimen for the tests ordered by the primary care provider

Physical dependence an expected physical response when a client who is on long-term opioid therapy has the opioid significantly reduced or withdrawn

Physical restraints any manual method or physical or mechanical device, material, or equipment attached to a client's body that cannot be removed easily and that restricts the client's movement

Physiologic dependence biochemical changes occurring in the body as a result of excessive use of a drug

PIE an acronym for a charting model that follows a recording sequence of *problems*, *interventions*, and *evaluation* of the effectiveness of the interventions

Piggyback a secondary IV setup that connects a second container to the tubing of a primary container at the upper port; used solely for intermittent drug administration

Pilates method of physical movement and exercise designed to stretch, strengthen, and balance the body, in particular the core of the body

Pilot study a "rehearsal" before the actual study begins, consisting of testing the study with a small sample or over a short period of time

Pinna *see* Auricle

Pitch the frequency (number of the vibrations per second) heard during auscultation

Pitting edema edema in which firm finger pressure on the skin produces an indentation (pit) that remains for several seconds

Placebo any medication or procedure that produces an effect in a client because of its implicit or explicit intent, and not because of its specific physical or chemical properties

Placenta a flat, disc-shaped organ that is highly vascular and normally forms in the upper segment of the endometrium of the uterus; exchanges nutrients and gases between the fetus and the mother

Plaintiff an individual claiming infringement of legal rights by one or more individuals

Planned change an intended, purposive attempt by an individual, group, organization, or larger social system to influence its own status quo or that of another organism or situation

Planning an ongoing process that involves (a) assessing a situation, (b) establishing goals and objectives based on assessment of a situation or future trends, and (c) developing a plan of action that identifies priorities, delineates who is responsible, determines deadlines, and describes how the intended outcome is to be achieved and evaluated

Plantar wart a wart on the sole of the foot

Plaque an invisible soft film consisting of bacteria, molecules of saliva, and remnants of epithelial cells and leukocytes that adheres to the enamel surface of teeth

Plasma the fluid portion of the blood in which the blood cells are suspended

Plateau a maintained concentration of a drug in the plasma during a series of scheduled doses

Pleural effusion exists when there is excessive fluid in the pleural space

Pleximeter in percussion, the middle finger of the dominant hand that is placed firmly on the client's skin

Plexor in percussion, the middle finger of the nondominant hand or a percussion hammer used to strike the pleximeter

Pneumothorax accumulation of air in the pleural space

Point of maximal impulse (PMI) the point where the apex of the heart touches the anterior chest wall and heart movements are most easily observed and palpated

Policies rules developed to govern the handling of frequently occurring situations

Polycythemia a condition in which clients with chronic hypoxia may develop higher than normal counts of red blood cells

Polydipsia excessive thirst

Polypnea abnormally fast respirations

Polysaccharides a branched chain of dozens, sometimes hundreds, of glucose molecules; starches

Polysomnography method for measuring sleep in which an electroencephalogram (EEG), electromyogram (EMG), and electro-oculogram (EOG) are recorded simultaneously for the purpose of assessing a client's activity during sleep

Polyunsaturated fatty acids fatty acid with more than one double bond (or many carbons not bonded to a hydrogen atom)

Polyuria refers to the production of abnormally large amounts of urine by the kidneys; also known as *diuresis*

Population includes all possible members of a group who meet the criteria for a study

Positive feedback feedback that stimulates change

Positive reinforcement giving rewards such as praise for a learner's achievements

Positron emission tomography (PET) a noninvasive radiologic study that involves the injection or inhalation of a radioisotope

Postmortem examination *see* Autopsy

Postoperative phase the period of surgery that begins with the admission of a client to the postanesthesia area and ends when healing is complete

Postural drainage positioning of a client to allow the drainage, by gravity, of secretions from the lungs

Postvoid residual (PVR) urine remaining in the bladder following voiding

Potentiating effect the increased effect of one or both drugs

Practice discipline field of study in which the central focus is performance of a professional role (nursing, teaching, management, making music)

Prayer human experience and communication with the divine

Preceptor an experienced nurse who assists the novice nurse in improving nursing skill and judgment

Precontemplation stage an individual typically denies having a problem and instead views others as having a problem and therefore wants to change the other individual's behavior

Precordium an area of the chest overlying the heart

Preemptive analgesia the administration of analgesics prior to an invasive or operative procedure in order to treat pain before it occurs

Preferred provider arrangements (PPAs) similar to preferred provider organizations, but PPAs can contract with individual healthcare providers; the plan can be limited or unlimited

Preferred provider organization (PPO) a group of physicians or a hospital that provides companies with health services at a discounted rate

Prefilled unit-dose system disposable units that provide injectable medications that are available as prefilled syringes ready for use, or as prefilled sterile cartridges and needles that require the attachment of a reusable holder before use

Prejudice preconceived notion or judgment that is not based on sufficient knowledge; it may be favorable or unfavorable

Preload the degree to which muscle fibers in the ventricle are stretched at the end of diastole

Preoperative phase the period of surgery that begins when the decision for surgery has been made and ends when the client is transferred to the operating room bed

Preparation stage occurs when the individual undertakes cognitive and behavioral activities that prepare him or her for change

Presbycusis generalized loss of hearing related to aging

Presbyopia loss of elasticity of the lens and thus loss of ability to see close objects as a result of the aging process

Prescription the written direction for the preparation and administration of a drug

Presencing a term describing the art of being present, or just being with a client during his or her suffering

Pressure injuries consist of injury to the skin or underlying tissue, usually over a bony prominence, as a result of force alone or in combination with movement; previously called *pressure ulcers*, *decubitus ulcers*, *pressure sores*, or *bedsores*

Primary care (PC) the point of entry into the healthcare system at which initial healthcare is given

Primary healthcare (PHC) essential healthcare based on practical, scientifically sound, and socially acceptable methods and technology made universally accessible to individuals and families in the community through their full participation and at a cost that the community and country can afford to maintain at every stage of their development in the spirit of self-reliance and self-determination

Primary intention healing tissue surfaces are approximated (closed) and there is minimal or no tissue loss, formation of minimal granulation tissue and scarring

Primary prevention activities directed toward the protection from or avoidance of potential health risks

Primary sexual characteristics relate to the organs necessary for reproduction, such as the testes, penis, vagina, and uterus

Principles-based (deontological) theories emphasize individual rights, duties, and obligations

Priority setting the process of establishing a preferential order for nursing strategies

Private law the body of law that deals with relationships between private individuals

Prn order "as needed order"; permits the nurse to give a medication when, in the nurse's judgment, the client requires it

Problem-oriented medical record (POMR) data about the client are recorded and arranged according to the client's problems, rather than according to the source of the information

Problem-oriented record (POR) *see* Problem-oriented medical record (POMR)

Problem solving obtaining information that clarifies the nature of the problem and suggests possible solutions

Procedures steps used in carrying out policies or activities

Process evaluation a component of quality assurance that focuses on how care was given

Process recording the verbatim (word-for-word) account of a conversation

Proctoscopy the viewing of the rectum

Proctosigmoidoscopy the viewing of the rectum and sigmoid colon

Profession an occupation that requires extensive education or a calling that requires special knowledge, skill, and preparation

Professional identity sense of oneself that is influenced by characteristics, norms, and values of the nursing discipline, resulting in an individual thinking, acting, and feeling like a nurse

Professional values values acquired during socialization into nursing from codes of ethics, nursing experiences, teachers, and peers

Progress notes chart entries made by a variety of methods and by all health professionals involved in a client's care for the purpose of describing a client's problems, treatments, and progress toward desired outcomes

Prone position position in which a client lies on his or her abdomen with the head turned to one side

Proprioception awareness of posture, movement, and changes in equilibrium; knowledge of position, weight, and resistance of objects in relation to the body

Proprioceptors sensory receptors that are sensitive to movement and the position of the body

Protein-calorie malnutrition (PCM) an imbalance between nutritional intake and the body's protein requirements

Protocols a predetermined and preprinted plan specifying the procedure to be followed in a particular situation

Proxemics distances that individuals allow between themselves and objects or other individuals

Psychologic dependence a state of emotional reliance on a drug to maintain one's well-being; a feeling of need or craving for a drug

Psychologic homeostasis emotional or psychologic balance or state of mental well-being

Psychomotor domain the "skill" domain; includes motor skills such as giving an injection

Puberty the first stage of adolescence in which sexual organs begin to grow and mature

Public law refers to the body of law that deals with relationships between individuals and the government and governmental agencies

Pulse the wave of blood within an artery that is created by contraction of the left ventricle of the heart

Pulse deficit the difference between the apical pulse and the radial pulse

Pulse oximeter a noninvasive device that measures the arterial blood oxygen saturation by means of a sensor attached to the finger or other location

Pulse pressure the difference between the systolic and the diastolic blood pressure

Pulse rhythm the pattern of the beats and intervals between the beats

Pulse volume the strength or amplitude of the pulse, the force of blood exerted with each heartbeat

Pureed diet a modification of the soft diet wherein liquid may be added to the food, which is then blended to a semisolid consistency

Purkinje fibers fibers of the ventricular conduction pathways that terminate in ventricular muscle, stimulating contraction

Purulent exudate an exudate consisting of leukocytes, liquefied dead tissue debris, and dead and living bacteria

Pus pooled exudates

Pyorrhea advanced periodontal disease in which teeth are loose and pus is evident when the gums are pressed

Pyrexia a body temperature above the normal range; fever

Qi body's vital energy

Qigong breathing and mental exercises combined with body movements

Qualifiers words that have been added to some NANDA labels to give additional meaning to the diagnostic statement

Qualitative research the systematic collection and thematic analysis of narrative data

Quality a subjective description of an auscultated sound (e.g., whistling, gurgling, or snapping)

Quality assurance (QA) program an ongoing systematic process designed to evaluate and promote excellence in the healthcare provided to clients

Quality improvement (QI) follows client care rather than organizational structure, focuses on process rather than individuals, and uses a systematic approach with the intention of improving the quality of care rather than ensuring the quality of care; also known as *continuous quality improvement* (CQI), *total quality management* (TQM), *performance improvement* (PI), or *persistent quality improvement* (PQI)

Quantitative research the systematic collection, statistical analysis, and interpretation of numerical data

Race classification of individuals according to shared biological characteristics and physical features

Racism refers to assumptions held about racial groups

Radiation the transfer of heat from the surface of one object to the surface of another without contact between the two objects

Radiopharmaceutical a pharmaceutical (targeted to a specific organ) labeled with a radioisotope, administered through various routes, to determine hyperfunction or hypofunction of the organ

Range of motion (ROM) the maximum degree of movement possible for each joint

Range orders medication orders in which the selected dose varies over a prescribed range according to the client's situation and status

Rapport a relationship between two or more individuals of mutual trust and understanding

Rationale the scientific reason for selecting a specific action

Reactive hyperemia a bright red flush on the skin occurring after pressure is relieved

Readiness behaviors or cues that reflect a learner's motivation to learn at a specific time

Reagent a substance used to produce a chemical reaction to detect or measure other substances

Recent memory deals with activities of the recent past of minutes to a few hours

Receptor a location on the surface of a cell membrane or within a cell (usually a protein) to which a drug chemically binds

Reconstitution the technique of adding a diluent to a powdered drug to prepare it for administration

Record a written communication providing formal, legal documentation of a client's progress

Recording the process of making written entries about a client on the medical record

Red blood cell (RBC) count number of red blood cells per cubic millimeter of whole blood

Red blood cell (RBC) indices evaluate size, weight, and hemoglobin concentrations of RBCs

Refeeding syndrome a combination of fluid and electrolyte shifts that can occur after a lengthy period of malnutrition or starvation that is a rare but potentially fatal complication of tube feeding

Referred pain pain perceived to be in one area but whose source is another area

Reflection thinking from a critical point of view, analyzing why one acted in a certain way, and assessing the results of one's actions

Reflex an automatic response of the body to a stimulus

Reflexology a treatment based on massage of the feet to relieve symptoms in other parts of the body

Reflux backward flow

Regeneration renewal, regrowth, the replacement of destroyed tissue cells by cells that are identical or similar in structure and function

Regional anesthesia the temporary interruption of the transmission of nerve impulses to and from a specific area or region of the body; the client loses sensation in an area of the body but remains conscious

Registry private duty agency that contracts with individual practitioners

Regression a defense mechanism in which one adapts behavior that was comforting earlier in life to overcome the discomfort and insecurity of the present situation

Regurgitation the spitting up or backward flow of undigested food

Relapsing fever the occurrence of short febrile periods of a few days interspersed with periods of 1 or 2 days of normal temperature

Relationships-based (caring) theories emphasize courage, generosity, commitment, and the need to nurture and maintain relationships

Relaxation response (RR) physiologic state achieved through deep relaxation breathing

Reliability the degree to which an instrument produces consistent results on repeated use

Religion an organized system of worship

REM sleep sleep during which the individual experiences *rapid eye movements*

Remission a period during a chronic illness when there is a lessening of severity or cessation of symptoms

Remittent fever the occurrence of a wide range of temperature fluctuations, more than 2°C (3.6°F) over a 24-hour period, all of which are above normal

Renin-angiotensin-aldosterone system system initiated by specialized receptors in the juxtaglomerular cells of the kidney nephrons that respond to changes in renal perfusion

Report oral, written, or computer-based communication intended to convey information to others

Repression a defense mechanism in which painful thoughts, experiences, and impulses are removed from awareness

Research entails using formal and systematic processes to solve problems and answer questions

Research design overall structure or blueprint or the general layout of a study

Research process method in which decisions are made that result in a detailed plan or proposal for a study, as well as the actual implementation of the plan

Reservoir a source of microorganisms

Resident flora microorganisms that normally reside on the skin and mucous membranes, and inside the respiratory and gastrointestinal tracts

Res ipsa loquitur "the thing that speaks for itself"; a legal doctrine that relates to negligence in which the harm cannot be traced to a specific healthcare provider or standard but does not normally occur unless there has been a negligent act

Resolution phase the part of the response cycle period of return to the unaroused state, which may last 10 to 15 minutes after orgasm, or longer if there is no orgasm

Resonance a hollow sound as produced by lungs filled with air during percussion

Respiration the act of breathing; includes the intake of oxygen and the output of carbon dioxide from the cells to the atmosphere

Respiratory acidosis (hypercapnia) a state of excess carbon dioxide in the body

Respiratory alkalosis a state of excessive loss of carbon dioxide from the body

Respiratory character *see* Respiratory quality

Respiratory hygiene or cough etiquette calls for covering the mouth and nose when sneezing or coughing, proper disposal of tissues, and separating potentially infected individuals from others by at least 1 m (3 ft) or having them wear a surgical mask

Respiratory membrane where gas exchange occurs between the air on the alveolar side and the blood on the capillary side; the alveolar and capillary walls form the respiratory membrane

Respiratory quality refers to those aspects of breathing that are different from normal, effortless breathing; includes the amount of effort exerted to breathe and the sounds produced by breathing

Respiratory rhythm refers to the regularity of expirations and inspirations

Respondeat superior a legal term meaning "let the master answer"; an employer assumes responsibility for the conduct of its employees and can also be held responsible for malpractice by employees

Responsibility the specific accountability or liability associated with the performance of duties of a particular role

Resting energy expenditure (REE) the amount of energy required to maintain basic body functions

Resting tremor a tremor that is apparent when the client is at rest and diminishes with activity

Restraints devices used to reduce or prevent physical activity of a client or a part of the body when the client is unable to remove the device

Retrograde pyelography a radiographic study used to evaluate the urinary tract

Retrospective audit evaluation of a client's record after discharge from an agency

Review of systems *see* Screening examination

Right (legal) a privilege or fundamental power to which an individual is entitled unless it is revoked by law or given up voluntarily

Rigor mortis stiffening of the body that occurs 2 to 4 hours after death

Risk factors factors that cause a client to be vulnerable to developing a health problem

Risk management having in place a system to reduce danger to clients and staff

Risk nursing diagnosis clinical judgment that a problem does not exist, but the presence of risk factors indicates that a problem is likely to develop unless nurses intervene

Role the set of expectations about how an individual occupying a specific position behaves

Role ambiguity unclear role expectations; individuals do not know what to do or how to do it and are unable to predict the reactions of others to their behavior

Role conflict a clash between the beliefs or behaviors imposed by two or more roles fulfilled by an individual

Role development involves socialization into a particular role

Role mastery performance of role behaviors that meet social expectations

Role model providing an example of acceptable behavior(s) through demonstration

Role performance what an individual does in a particular role in relation to the behaviors expected of that role

Role strain a generalized state of frustration or anxiety experienced with the stress of role conflict and ambiguity

Root cause analysis process for identifying factors that bring about deviations in practices that lead to an event

S_1 the first heart sound; occurs when the atrioventricular valves (mitral and tricuspid) close

S_2 the second heart sound; occurs when the semilunar valves (aortic and pulmonic) close

Safety monitoring device an electronic sensor or monitor that detects when clients are attempting to get out of a bed or chair and triggers an alarm

Safety-net hospitals hospitals that provide a significant level of care to low-income, uninsured, and vulnerable populations

Sairy Gamp a character in the Charles Dickens book *Martin Chizzlewit* who represented the negative image of nurses in the early 1800s

Saliva the clear liquid secreted by the salivary glands in the mouth

Sample (statistics) segment of the population from whom data will be collected

Sanguineous exudate an exudate containing large amounts of red blood cells

Sarcopenia steady decrease in muscle fibers

Saturated fatty acids those in which all carbon atoms are filled to capacity (i.e., saturated) with hydrogen

Scabies a contagious skin infestation by the itch mite that produces intense itching, especially at night

Scald a burn from a hot liquid or vapor, such as steam

Scientific health belief based on the belief that life and life processes are controlled by physical and biochemical processes that can be manipulated by humans

Scientific validation thorough critique of a study for its conceptual and methodological integrity

Screening examination a brief review of essential functioning of various body parts or systems; also called *review of systems*

Scrub person usually UAP but can be an RN or LPN; assists the surgeons by draping the client with sterile drapes and handling sterile instruments and supplies; with the circulating nurse, is responsible for accounting for all sponges, needles, and instruments at the close of surgery

Sebaceous glands active under the influence of androgens in both males and females, which secrete sebum and become most active on the face, neck, shoulder, upper back, and chest; are often the cause of an increased incidence of acne

Sebum the oily, lubricating secretion of sebaceous glands in the skin

Seclusion the involuntary confinement of a client alone in a room or area from which the client is physically prevented from leaving

Secondary intention healing wound in which the tissue surfaces are not approximated and there is extensive tissue loss; formation of excessive granulation tissue and scarring

Secondary prevention activities designed for early diagnosis and treatment of disease or illness

Secondary sexual characteristics physical characteristics that differentiate the male from the female but do not relate directly to reproduction

Seizure a sudden onset of excessive electrical discharges in one or more areas of the brain

Seizure precautions safety measures taken to protect clients from injury should they have a seizure

Selectively permeable cell membranes that allow substances to move across them with varying degrees of ease

Self-awareness the relationship between an individual's own and others' perception of self

Self-concept the collection of ideas, feelings, and beliefs one has about oneself

Self-esteem the value one has for oneself; self-confidence

Self-regulation homeostatic mechanisms that come into play automatically in the healthy individual

Semicircular canals in the inner ear; contain the organs of equilibrium

Semi-Fowler's position a bed-sitting position in which the head and trunk are raised 15° to 45°, typically at a 30° angle of elevation; sometimes called *low Fowler's position*

Semilunar valves crescent moon-shaped valves between the cardiac ventricles and the pulmonary artery (pulmonic valve) and the aorta (aortic valve)

Sensorineural hearing loss the result of damage to the inner ear, the auditory nerve, or the hearing center in the brain

Sensoristasis the need for sensory stimulation

Sensory deficit partial or complete impairment of any sensory organ

Sensory deprivation insufficient sensory stimulation for an individual to function

Sensory memory momentary perception of stimuli by the senses

Sensory overload an overabundance of sensory stimulation

Sensory perception the organization and translation of stimuli into meaningful information

Sensory reception process of receiving environmental stimuli

Sentinel event an unexpected occurrence that results in death, permanent harm or severe temporary harm, and intervention required to sustain life

Separation anxiety the fear and frustration experienced by young children that comes with parental absences

Sepsis the presence of pathogenic organisms or their toxins in the blood or body tissues

Septicemia occurs when bacteremia results in systemic infection

Septum a dividing structure such as that between the cardiac chambers or between the two sides of the nose

Serosanguineous blood-tinged drainage seeped from wounds healing by secondary intention

Serous exudate consists chiefly of serum (the clear portion of the blood)

Serum osmolality a measure of the solute concentration of the blood

Severe pain pain in the 7 to 10 range on a numeric scale of 0 (no pain) to 10 (worst pain imaginable)

Sexual orientation the preference of an individual for one gender or the other

Sexual self-concept how one values oneself as a sexual being

Shaft the part of the needle that is attached to the hub; also called the *cannula*

Shaken baby syndrome (SBS) *see* Abusive head trauma

Shared governance a method that aims to distribute decision making among a group of individuals

Shared leadership a contemporary theory of leadership that recognizes the leadership capabilities of each member in a professional group and assumes that appropriate leadership will emerge in relation to the challenges that confront the group

Shared medical decision making a process whereby the primary healthcare provider gives the client the relevant information for all treatment alternatives, and the client provides the primary healthcare provider relevant personal information that might make one treatment or therapy more appropriate for the individual client

Shearing force a combination of friction and pressure that, when applied to the skin, results in damage to the blood vessels and tissues

Shock phase first part of the alarm reaction in which the stressor may be perceived consciously or unconsciously by the individual

Short-term memory information held in the brain for immediate use or what one has in mind at a given moment

Shroud a large piece of plastic or cotton material used to enclose a body after death

Side effect the secondary effect of a drug that is unintended; usually predictable and may be either harmless or potentially harmful

Signs detectable by an observer or can be measured or tested against an accepted standard; can be seen, heard, felt, or smelled; also called *objective data*

Sims' position side-lying position with lowermost arm behind the body and the upper arm at the shoulder and the elbow, with the client's legs flexed in front

Single order an order that is to be carried out one time only at a specified time

Sinoatrial (SA or sinus) node the primary pacemaker of the heart located where the superior vena cava enters the right atrium

Situational leader adapts style according to consideration of the staff members' abilities, knowledge of the nature of the task to be done, and sensitivity to the context or environment in which the task takes place

Situation, background, assessment, and recommendation (SBAR) process a structured approach to documentation used when nurses communicate with primary care providers and other nurses about client status

Sitz bath a bath in which the client sits in warm water to help soothe and heal the perineum

Skinfold measurement an indicator of the amount of body fat, the main form of stored energy

Slander defamation by the spoken word, stating unprivileged (not legally protected) or false words by which a reputation is damaged

Sleep an altered state of consciousness in which the individual's perception of and reaction to the environment are decreased

Sleep apnea frequent short breathing pauses during sleep

Sleep architecture basic organization of normal sleep

Sleep hygiene refers to interventions used to promote sleep

Small calorie (c, cal) the amount of heat required to raise the temperature of 1 g of water 1°C

SOAP an acronym for a charting method that follows a recording sequence of *subjective* data, *objective* data, *assessment*, and *planning*

Socratic questioning a technique one can use to look beneath the surface, recognize and examine assumptions, search for inconsistencies, examine multiple points of view, and differentiate what one knows from what one merely believes

Sojourner Truth an abolitionist, Underground Railroad agent, preacher, and women's rights advocate, she was a nurse for more than 4 years during the Civil War and worked as a nurse and counselor for the Freedman's Relief Association after the war

Solutes substances dissolved in a liquid

Solvent the liquid in which a solute is dissolved

Somatic pain originates in the skin, muscles, bone, or connective tissue

Sordes accumulation of foul matter (food, microorganisms, and epithelial elements) on the teeth and gums

Source-oriented record a record in which each healthcare provider or department makes notations in a separate section or sections of the client's chart

Spastic describing the sudden, prolonged involuntary muscle contractions of clients with damage to the central nervous system

Specific defenses immune functions directed against identifiable bacteria, viruses, fungi, or other infectious agents; also called *immune defenses*

Specific gravity the weight or degree of concentration of a substance compared with that of an equal volume of another, such as distilled water, taken as a standard

Specific self-esteem how much one approves of a certain part of oneself

Sphygmomanometer a device used to measure blood pressure

Spinal anesthesia anesthesia produced by injecting an anesthetic agent into the subarachnoid space surrounding the spinal cord; also referred to as a *subarachnoid block (SAB)*

Spiritual care describes ways in which nurses can offer spiritual support to clients

Spiritual disruption refers to the inner chaos that can occur when an individual's religious assumptions and beliefs are threatened or shattered

Spiritual health *see* Spiritual wellness or well-being

Spirituality the human tendency to seek meaning and purpose in life, inner peace and acceptance, forgiveness and harmony, hope, beauty, and so forth; includes the drive to become all that one can be and is bound to intuition, creativity, and motivation

Spiritual or religious coping refers to the spiritual beliefs or ways of thinking that help individuals cope with their challenges; can be both positive and negative

Spiritual wellness or well-being results when individuals intentionally seek to strengthen their spiritual muscles, as it were, through various spiritual disciplines (e.g., prayer, meditation, service, fellowship with similar believers, learning from a spiritual mentor, worship, study, fasting)

Sputum the mucous secretion from the lungs, bronchi, and trachea

Stage of exhaustion the third stage in the adaptation syndromes that occurs when the adaptation that the body made during the second stage cannot be maintained

Stage of resistance the second stage in the adaptation syndromes when the body's adaptation takes place

Standard a generally accepted rule, model, pattern, or measure

Standardized care plan formal plan that specifies the nursing care for groups of clients with common needs (e.g., all clients with myocardial infarction)

Standard precautions (SP) the risk of caregiver exposure to client body tissues and fluids rather than the suspected presence or absence of infectious organisms determines the use of clean gloves, gowns, masks, and eye protection

Standards of care the skills and learning commonly possessed by members of a profession

Standards of practice descriptions of the responsibilities for which nurses are accountable

Standards of professional performance as set by the American Nurses Association (ANA), describe behaviors expected in the professional nursing role

Standing order an order that may be carried out indefinitely until another order is written to cancel it, or that may be carried out for a specified number of days

Stapes stirrups bone of the middle ear

Statistically significant term applied after data have been analyzed to determine whether the results had a probability less than 0.05, which is considered the acceptable level of significance

Stat order indicates an order that is to be carried out immediately and only once

Statutory laws laws enacted by any legislative body

Steatorrhea excessive amount of fat in the stool due to a malabsorption syndrome or pancreatic enzyme deficiency

Stereognosis the ability to recognize objects by touching and manipulating them

Stereotyping refers to making the assumption that an individual reflects all characteristics associated with being a member of a group

Sterile field a microorganism-free area

Sterile technique practices that keep an area or object free of all microorganisms; also called *surgical asepsis*

Sterilization a process that destroys all microorganisms, including spores and viruses

Sternum the breastbone

Stimulus-based stress model stress is defined as a stimulus, life event, or set of circumstances that arouses physiologic or psychologic reactions that may increase the individual's vulnerability to illness

Stoma an opening created in the abdominal wall by an ostomy

Stool *see* Feces

Strabismus cross-eye

Stress a condition in which an individual experiences changes in the normal balanced state

Stress electrocardiography uses ECGs to assess a client's response to an increased cardiac workload during exercise

Stressor any event or stimulus that causes an individual to experience stress

Stridor a harsh, crowing sound made on inhalation caused by constriction of the upper airway

Strike an organized work stoppage by a group of employees to express a grievance, enforce a demand for changes in condition of employment, or solve a dispute with management

Stroke volume (SV) the amount of blood ejected with each cardiac contraction

Structure evaluation focuses on the setting in which care is given

Subarachnoid block (SAB) *see* Spinal anesthesia

Subculture usually composed of individuals who have a distinct identity and yet are related to a larger cultural group

Subcutaneous beneath the layers of the skin; hypodermic

Subjective data data that are apparent only to the individual affected; can be described or verified only by that individual; also referred to as *symptoms*

Sublingual a method of drug administration in which the drug is placed under the tongue

Substance abuse disorder (SUD) a pattern of behaviors that range from misuse to dependency or addiction to alcohol or drugs

Suctioning the aspiration of secretions through a catheter connected to a suction machine or wall suction outlet

Sudden infant death syndrome (SIDS) the sudden and unexpected death of an infant

Superego the conscience of personality; the source of feelings of guilt, shame, and inhibition

Supine position position in which the head and shoulders are not elevated; also called the *dorsal position*

Supplemental Security Income (SSI) special payments for individuals with disabilities, those who are blind, and those who are not eligible for Social Security; these payments are not restricted to healthcare costs

Suppositories solid, cone-shaped, medicated substances inserted into the rectum, vagina, or urethra

Suppuration the formation of pus

Suprapubic catheter an indwelling catheter that has been surgically placed in the bladder through the abdominal wall, either with or without a urethrally placed catheter

Surface anesthesia *see* Topical anesthesia

Surface temperature the temperature of tissue, the subcutaneous tissue, and fat

Surfactant a surface-active agent (e.g., soap or a synthetic detergent); in pulmonary physiology, a mixture of phospholipids secreted by alveolar cells into the alveoli and respiratory air passages that reduces the surface tension of pulmonary fluids and thus contributes to the elastic properties of pulmonary tissue

Surgical asepsis practices that keep an area or object free of all microorganisms; also called *sterile technique*

Suture a thread used to sew body tissues together

Sutures junction lines of the skull bones

Symptoms *see* Subjective data

Syndrome diagnosis a diagnosis that is associated with a cluster of other diagnoses

Synergistic effect when two different drugs increase the action of one or another drug

System a set of interacting identifiable parts or components

Systemic infection occurs when pathogens spread and damage different parts of the body

Systole the period during which the ventricles contract

Systolic pressure the pressure of the blood against the arterial walls when the ventricles of the heart contract

Tachycardia an abnormally rapid pulse rate; greater than 100 beats per minute

Tachypnea abnormally fast respirations; usually more than 24 respirations per minute

Tactile related to touch

T'ai chi discipline that combines physical fitness, meditation, and self-defense

Target population the universe of elements to which the researcher wishes to be able to apply the study's findings

Tartar a visible, hard deposit of plaque and dead bacteria that forms at the gum lines

Taxonomy a classification system or set of categories, such as nursing diagnoses, arranged on the basis of a single principle or consistent set of principles

Teacher a nurse who helps clients learn about their health and the healthcare procedures they need to perform to restore or maintain their health

Teaching system of activities intended to produce learning

Team nursing the delivery of individualized nursing care to clients by a team led by a professional nurse

Technical skills "hands-on" skills such as those required to manipulate equipment, administer injections, and move or reposition clients

Telehealth delivery of health-related services and information via telecommunication technologies

Telemedicine technology used to transmit electronic medical data about clients to individuals at distant locations

Telenursing use of technology to provide nursing practice at a distance

Temperament the way individuals respond to their external and internal environment

Teratogen anything that adversely affects normal cellular development in the embryo or fetus

Termination stage the ultimate goal where the individual has complete confidence that the problem is no longer a temptation or threat

Territoriality a concept of the space and things that individuals consider their own

Tertiary intention healing healing that occurs in wounds left open for 3 to 5 days and then closed with sutures, staples, or adhesive skin closures

Tertiary prevention activities designed to restore individuals with disabilities to their optimal level of functioning

Theory a system of ideas that is proposed to explain a given phenomenon (e.g., theory of gravity)

Therapeutic bath a bath given for physical effects, such as to soothe irritated skin or to promote healing of an area (e.g., the perineum); two common types are the sitz bath and the medicated bath

Therapeutic communication an interactive process between nurse and client that helps the client overcome temporary stress, get along with other people, adjust to the unalterable, and overcome psychologic blocks that stand in the way of self-realization

Therapeutic effect the primary effect intended of a drug; reason the drug is prescribed

Third space syndrome fluid shifts from the vascular space into an area where it is not readily accessible as extracellular fluid

Thoracentesis a procedure to remove excess fluid or air from the pleural cavity to ease breathing or to introduce chemotherapeutic drugs intrapleurally

Thrill a vibrating sensation over a blood vessel that indicates turbulent blood flow

Thrombophlebitis inflammation of a vein followed by formation of a blood clot

Thrombus a solid mass of blood constituents in the circulatory system; a clot (plural: *thrombi*)

Throughput a transformation that occurs after input is absorbed by the system and is then processed in a way that is useful to the system

Ticks small gray-brown parasites that bite into tissue and suck blood and transmit several diseases to individuals, in particular Rocky Mountain spotted fever, Lyme disease, and tularemia

Tidal volume the volume of air that is normally inhaled and exhaled

Tinea pedis athlete's foot (ringworm of the foot), which is caused by a fungus

Tissue perfusion passage of fluid (e.g., blood) through a specific organ or body part

Tolerance occurs when the client's opioid dose, over time, leads to a decreased sensitivity to the drug's analgesic effect and increasing doses of the opioid are needed to provide the same level of pain relief

Topical applied externally (e.g., to the skin or mucous membranes)

Topical anesthesia applied directly to the skin and mucous membranes, open skin surfaces, wounds, and burns; also called *surface anesthesia*

Top-level managers organizational executives primarily responsible for establishing goals and developing strategic plans

Tort a civil wrong committed against an individual or an individual's property

Tort law law that defines and enforces duties and rights among private individuals that are not based on contractual agreements

Trade name name of the drug given by the drug manufacturer; also known as a *brand name*

Traditional refers to those customs, beliefs, or practices that have existed for many generations without changing

Traditional Chinese medicine (TCM) based on the premise that the body's vital energy circulates through pathways or meridians and can be accessed and manipulated through specific anatomic points along the surface of the body

Tragus the cartilaginous protrusion at the entrance to the ear canal

Transactional leader a contemporary theory of leadership in which resources are exchanged as an incentive for loyalty and performance

Transactional stress theory a theory that encompasses a set of cognitive, affective, and adaptive (coping) responses that arise out of person–environment transactions; the person and the environment are inseparable and affect each other

Transcultural nursing providing care within the differences and similarities of the beliefs, values, and patterns of cultures

Transcutaneous electrical nerve stimulation (TENS) a method of applying low-voltage electrical stimulation directly over pain areas

Transdermal patch a dermatologic medication delivery system that administers sustained-action medications via multilayered films containing the drug and an adhesive layer

Transformational leader leader who fosters creativity, risk taking, commitment, and collaboration by empowering the group to share in the organization's vision

Transgender someone who identifies with a different gender than his or her anatomic designation

Translator an individual who converts written material (such as client education pamphlets) from one language into another

Tremor an involuntary trembling of a limb or body part

Trial the period during which all relevant facts are presented to a jury or judge

Trial and error way to solve problems in which a number of approaches are tried until a solution is found

Triangular fossa a depression of the antihelix

Triglycerides substances that have three fatty acids; they account for more than 90% of the lipids in food and in the body

Trigone a triangular area at the base of the bladder marked by the ureter openings at the posterior corners and the opening of the urethra at the anterior corner

Trimesters the 3-month periods during pregnancy marking certain landmarks for developmental changes in mother and the fetus; three trimesters occur during a pregnancy

Tripod (triangle) position the proper standing position with crutches; crutches are placed about 15 cm (6 in.) in front of the feet and out laterally about 15 cm (6 in.), creating a wide base of support

Trocar a sharp, pointed instrument

Troponin enzyme that is released into the blood during a myocardial infarction

Trough level represents the lowest concentration of a drug in the blood serum

Tuberculin syringe a narrow syringe, calibrated in tenths and hundredths of a milliliter on one scale and in sixteenths of a minim on the other scale that can be useful in administering other drugs, particularly when small or precise measurement is indicated

Two-point discrimination *see* One-point discrimination

Tympanic membrane the eardrum

Tympany a musical or drumlike sound produced during percussion over an air-filled stomach

Ultrasonography the use of ultrasound to produce an image of an organ or tissue

Unconscious mind the mental life of an individual of which the individual is unaware

Undernutrition intake of nutrients insufficient to meet daily energy requirements as a result of inadequate food intake or improper digestion and absorption of food

Undertaker *see* Mortician

Universal precautions (UP) An earlier term for standard precautions that some agencies may use, reflecting their applicability in all client care situations

Unplanned change haphazard change that occurs without control by any individual or group

Unprofessional conduct one of the grounds for action against a nurse's license; includes incompetence or gross negligence, conviction of practicing without a license, falsification of client records, and illegally obtaining, using, or possessing controlled substances

Unsaturated fatty acid a fatty acid that could accommodate more hydrogen atoms than it currently does

Upper-level managers organizational executives who are primarily responsible for establishing goals and developing strategic plans

Urea a substance found in urine, blood, and lymph; the main nitrogenous substance in blood

Ureterostomy type of urinary diversion that involves surgery of the ureters

Urgency the feeling that one must urinate

Urinary frequency the need to urinate often

Urinary hesitancy a delay and difficulty in initiating voiding; often associated with dysuria

Urinary incontinence a temporary or permanent inability of the external sphincter muscles to control the flow of urine from the bladder

Urinary reflux backward flow of urine

Urinary retention the accumulation of urine in the bladder and inability of the bladder to empty itself

Urinary stasis stagnation of urinary flow

Urination the process of emptying the bladder; also called *micturition* or *voiding*

Urine osmolality a measure of the solute concentration of urine, a more exact measurement of urine concentration than specific gravity

Utilitarianism a specific, consequence-based, ethical theory that judges as right the action that does the most good and least amount of harm for the greatest number of individuals; often used in making decisions about the funding and delivery of healthcare

Utility *see* Utilitarianism

Vaginismus involuntary spasm of outer one-third of vaginal muscles, making penetration of the vagina painful

Validation the determination that the diagnosis accurately reflects the problem of the client, that the methods used for data gathering were appropriate, and that the conclusion or diagnosis is justified by the data

Validity the degree to which an instrument measures what it is intended to measure

Valsalva maneuver forceful exhalation against a closed glottis, which increases intrathoracic pressure and thus interferes with venous blood return to the heart

Values something of worth; a belief held dearly by an individual

Values clarification a process by which individuals define their own value

Value system the organization of an individual's values along a continuum of relative importance

Variance a variation or deviation from a critical pathway; goals not met or interventions not performed according to the time frame

Vasoconstriction constricted blood vessels

Vasodilation an increase in the diameter of blood vessels

Vector-borne transmission transport of an infectious agent from an animal or flying or crawling insect that serves as an intermediate means via biting or depositing feces or other materials on the skin

Vehicle-borne transmission transport of an infectious agent into a susceptible host via any intermediate substance (e.g., fomites or food)

Venipuncture puncture of a vein for collection of a blood specimen or for infusion of therapeutic solutions

Ventilation the movement of air in and out of the lungs; the process of inhalation and exhalation

Ventricles two lower chambers of the heart

Veracity a moral principle that holds that one should tell the truth and not lie

Verbal communication use of verbal language to send and receive messages

Verdict the outcome made by a jury

Vernix caseosa a protective covering that develops over the unborn fetus's skin; a white, cheese-like substance that adheres to the skin and can become 1/8 inch thick by birth

Vesicant a medication or fluid that causes blisters, severe tissue injury, or necrosis if it escapes from the vein

Vesicostomy surgical production of an opening into the bladder

Vestibule contains the organs of equilibrium; found in the inner ear

Vestibulitis severe pain on touch or attempted vaginal entry

Vial a small glass medication container with a sealed rubber cap; used for single or multiple doses

Vibration a series of vigorous quiverings produced by hands that are placed flat against the chest wall to loosen thick secretions

Virulence ability to produce disease

Viruses nucleic acid–based infectious agents

Visceral internal organs

Visceral pain pain arising from organs or hollow viscera

Vision the mental image of a possible and desirable future state

Visiting nursing *ee* Home health nursing care

Visual related to sight

Visual acuity the degree of detail the eye can discern in an image

Visual fields the area an individual can see when looking straight ahead

Vital capacity the maximum amount of air that can be exhaled after a maximum inhalation

Vital signs body temperature, pulse, respiration, and blood pressure. Many agencies have designated pain as the fifth vial sign

Vitamin an organic compound that cannot be manufactured by the body and is needed in small quantities to catalyze metabolic processes

Vitiligo patches of hypopigmented skin, caused by the destruction of melanocytes in the area

Voiding *see* urination

Volume control infusion set small fluid containers (100 to 150 mL in size) attached below a primary infusion container so that a medication can be administered through the client's IV line

Volume expanders used to increase the blood volume following severe loss of blood, or loss of plasma

Vulvodynia constant and unremitting burning of the vulva

Water-soluble vitamins vitamins that the body cannot store, so individuals must get a daily supply in the diet; include C and B-complex vitamins

Well-being reflection of the objective conditions in which choices are made and that shape individuals' abilities to transform resources into given ends, such as health

Wellness a state of well-being; engaging in attitudes and behaviors that enhance quality of life and maximize personal potential

Western medicine approach to health that focuses on the use of science in the diagnosis and treatment of health problems

White blood cell (WBC) count determines the number of circulating WBCs per cubic millimeter of whole blood

Xerostomia dry mouth as a result of a reduced supply of saliva

Yoga a type of meditation that is a system of exercises for attaining bodily or mental control and well-being

Index

Note: Page numbers followed by *f* indicate figures; those followed by *t* indicate tables, boxes, or special features

Potential for Decline in Health, 1133
Sensory-Perception Disturbance, 981
Sleep, 1155
Spiritual Disruption, 1036
Urinary Elimination, 1239

PRACTICE GUIDELINES

Administering Medications, 832
Applying Restraints, 722
Assessing Wounds, 900
Bandages or Binders, 920
Bandaging, 920
Bedmaking, 770
Bedpan, 1256
Bladder Retraining, 1221
Bloodborne Pathogens Exposure, 698
Cautions for Popular Herbal Preparations, 397
Central Vascular Access Device, 1375
Cleaning Wounds, 906
Colleague Accountability in Pain Management, 645
Common Pressure Sites, 896
Communication During Interview, 177
Damp Gauze Versus Advanced Dressings, 912
Documentation, 249
Facilitating Fluid Intake, 1370
Home Healthcare Documentation, 245
Individualizing Care, 641
Insertion of a Short Peripheral Catheter, 1373
Legal Protection for Nurses, 65
Long-Term Care Documentation, 245
N95 Respirator Mask, 688
Nasogastric or Gastrostomy Tube Medication Administration, 842
Passive ROM Exercises, 1123
Praying with Clients, 1029
Preventing Falls, 711
Religious Practices, 1030
Reporting a Crime, Tort, or Unsafe Practice, 65
Restricting Fluid Intake, 1370
Skin Care Preparations, 874
Spiritual Beliefs, 1028
Stretchers, 1118
Surgical Wounds, 900
Treating Wounds, 905
Using an Interpreter, 381
Vein Selection, 1372
Verbal Communication, 381
Voiding Habits, 1220
Wheelchair Safety, 1117

SKILLS

Administering an Enema, 1260
Administering an Intradermal Injection, 856
Administering an Intramuscular Injection, 865
Administering Medications Using IV Push, 870
Administering Ophthalmic Instillations, 874
Administering Oral Medications, 838
Administering Otic Instillations, 876
Administering Oxygen by Cannula, Face mask, or Face Tent, 1294
Administering a Subcutaneous Injection, 858
Administering a Tube Feeding, 1194
Administering Vaginal Instillations, 879
Applying and Removing Personal Protective Equipment (Gloves, Gown, Mask, Eyewear), 686
Applying and Removing Sterile Gloves (Open Method), 696
Applying Antiemboli Stockings, 943
Applying Restraints, 724
Assessing Abdomen, 601
Assessing Anus, 622
Assessing Apical Pulse, 522
Assessing Apical-Radial Pulse, 525
Assessing Appearance and Mental Status, 551
Assessing Blood Pressure, 535
Assessing Body Temperature, 514
Assessing Breasts and Axillae, 596
Assessing Ears and Hearing, 570
Assessing Eye Structures and Visual Acuity, 565
Assessing Female Genitals, 617
Assessing Hair, 559
Assessing Heart and Central Vessels, 591
Assessing Male Genitals, 620
Assessing Mouth and Oropharynx, 574
Assessing Musculoskeletal System, 605
Assessing Nails, 561
Assessing Neck, 579
Assessing Neurologic System, 609
Assessing Nose and Sinuses, 573
Assessing Peripheral Pulse, 520
Assessing Peripheral Vascular System, 594
Assessing Respirations, 529
Assessing Skin, 556
Assessing Skull and Face, 562
Assessing Thorax and Lungs, 585
Assisting Client to Ambulate, 1125
Bathing an Adult Client, 737
Bladder Irrigation, 1234
Brushing and Flossing Teeth, 754
Capillary Blood Specimen to Measure Blood Glucose, 786
Changing Bowel Diversion Ostomy Appliance, 1268
Changing an Intravenous Container and Tubing, 1389
Changing an Occupied Bed, 774
Changing an Unoccupied Bed, 771
Changing a Short Peripheral Catheter to an Intermittent Infusion Device, 1392
Cleaning a Sutured Wound and Dressing a Wound with a Drain, 908
Collecting Clean Catch Urine Sample, 792
Discontinuing an Intravenous Infusion and Removing a Short Peripheral Catheter, 1390
Establishing and Maintaining a Sterile Field, 692
Exit Safety Monitoring Device, 713
External Catheter, 1222
Gastrostomy or Jejunostomy Tube Feeding, 1197
Implementing Seizure Precautions, 714
Indwelling Urinary Catheterization, 1227
Initiating, Maintaining, and Terminating a Blood Transfusion Using a Y-Set, 1398
Inserting Nasogastric Tube, 1188
Irrigating a Wound, 910
Lateral or Prone Position, 1113
Logrolling a Client, 1114
Managing Gastrointestinal Suction, 958
Measuring Oxygen Saturation, 539
Mixing Medications Using Syringe, 854
Monitoring an Intravenous Infusion, 1387
Moving Client Up in Bed, 1112
Obtaining a Wound Drainage Specimen for Culture, 915
Oral, Oropharyngeal, Nasopharyngeal, and Nasotracheal Suctioning, 1304
Performing Hand Washing, 680
Preparing Medications from Ampules, 851
Preparing Medications from Vials, 852
Providing a Back Massage, 654
Providing Foot Care, 747
Providing Hair Care, 762
Providing Perineal-Genital Care, 742
Providing Special Oral Care, 757
Providing Tracheostomy Care, 1311
Removing a Nasogastric Tube, 1200
Removing, Cleaning, and Inserting a Hearing Aid, 767
Sequential Compression Devices, 1338
Sit on Side of Bed, 1115
Starting an Intravenous Infusion and Inserting a Short Peripheral Catheter, 1379
Suctioning a Tracheostomy or Endotracheal Tube, 1308
Teaching Moving, Leg Exercises, Deep Breathing, and Coughing, 937
Transferring Between Bed and Chair, 1118
Transferring Between Bed and Stretcher, 1120
